Abstract

On 2017 August 17 a binary neutron star coalescence candidate (later designated GW170817) with merger time 12:41:04 UTC was observed through gravitational waves by the Advanced LIGO and Advanced Virgo detectors. The *Fermi* Gamma-ray Burst Monitor independently detected a gamma-ray burst (GRB 170817A) with a time delay of $\sim$1.7 s with respect to the merger time. From the gravitational-wave signal, the source was initially localized to a sky region of 31 deg^2 at a luminosity distance of 40^{+8}_{-8} Mpc and with component masses consistent with neutron stars. The component masses were later measured to be in the range 0.86 to 2.26 $M_\odot$. An extensive observing campaign was launched across the electromagnetic spectrum leading to the discovery of a bright optical transient (SSS17a, now with the IAU identification of AT 2017gfo) in NGC 4993 (at $\sim$40 Mpc) less than 11 hours after the merger by the One-Meter, Two Hemisphere (1M2H) team using the 1 m Swope Telescope. The optical transient was independently detected by multiple teams within an hour. Subsequent observations targeted the object and its environment. Early ultraviolet observations revealed a blue transient that faded within 48 hours. Optical and infrared observations showed a redward evolution over $\sim$10 days. Following early non-detections, X-ray and radio emission were discovered at the transient's position $\sim$9 and $\sim$16 days, respectively, after the merger. Both the X-ray and radio emission likely arise from a physical process that is distinct from the one that generates the UV/optical/near-infrared emission. No ultra-high-energy gamma-rays and no neutrino candidates consistent with the source were found in follow-up searches. These observations support the hypothesis that GW170817 was produced by the merger of two neutron stars in NGC 4993 followed by a short gamma-ray burst (GRB 170817A) and a kilonova/macronova powered by the radioactive decay of r-process nuclei synthesized in the ejecta.

Searching for Dark Matter Interactions

Neutron Stars: The Optimal Direct Detection Experiment

Neutron Star

- 3×10^{30} kg
- 2×10^{10} days

6×10^{40} kg day

Xenon-1T

- **1000 kg**
- **700 days**
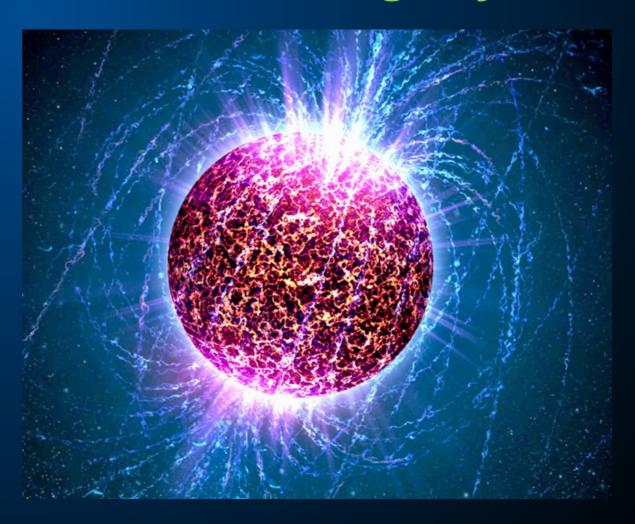

7×10^5 kg day

Neutron Stars: The Optimal Direct Detection Experiment
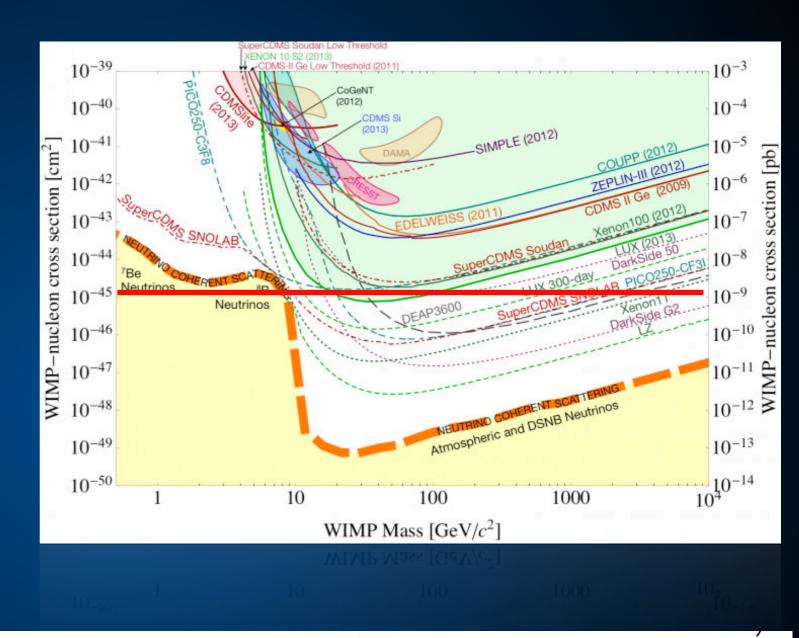

- **Neutron stars are so dense that they are optically thick to dark matter**

$$\sigma_{\text{sat}}^{\text{single}} \simeq \pi R^2 m_{\text{n}}/M \simeq 2 \times 10^{-45} \text{ cm}^2 \left(\frac{1.5 \text{ M}_\odot}{M}\right)\left(\frac{R}{10 \text{ km}}\right)^2$$

- **This saturates the sensitivity of neutron stars to dark matter**

Neutron Stars: Astrophysics Enhancements

- **Neutron stars gravitationally attract nearby dark matter**
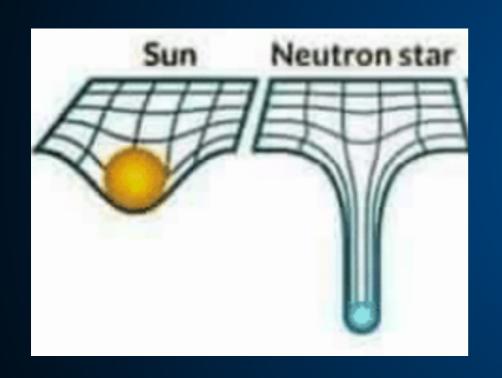

Capture radius is approximately 1 R_0

$$b_{\max} = \left(\frac{2GMR}{v_x^2}\right)^{1/2} \left(1 - \frac{2GM}{R}\right)^{-1/2}$$

$$\dot{m} = \pi b_{\max}^2 v_x \rho_x,$$

- **Interaction scales as v_x^{-1}, very sensitive to slowly moving dark matter**

Neutron Stars: Astrophysics Enhancements

- **Neutron stars are a dark matter collider**

When dark matter hits the neutron star surface it is moving relativistically:
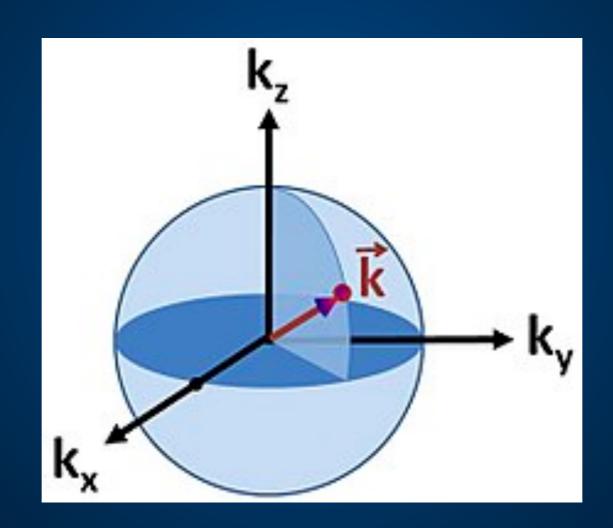

$$v_{esc} = \sqrt{\frac{2GM}{r}} \sim 0.7c$$

- **Can probe p-wave suppressed dark matter or dark matter mass splittings**

Neutron Stars: Particle Physics Complications

Typical NS neutron momentum is:

$$p_{\mathrm{F,n}} \simeq 0.45 \text{ GeV } (\rho_{NS}/(4 \times 10^{38} \text{ GeV cm}^{-3}))$$

This suppresses the interaction cross-section for low mass DM:

$$\sigma_{\mathrm{sat}}^{\mathrm{Pauli}} \simeq \pi R^2 m_{\mathrm{n}} p_{\mathrm{f}} / (M\gamma m_{\mathrm{x}} v_{\mathrm{esc}}) \simeq 2 \times 10^{-45} \text{ cm}^2 \left(\frac{\text{GeV}}{m_{\mathrm{x}}}\right) \left(\frac{1.5 \text{ M}_\odot}{M}\right) \left(\frac{R}{10 \text{ km}}\right)^2.$$

Neutron Stars: Particle Physics Complications

Dark Matter kinetic energy lost in a scatter with a proton is:
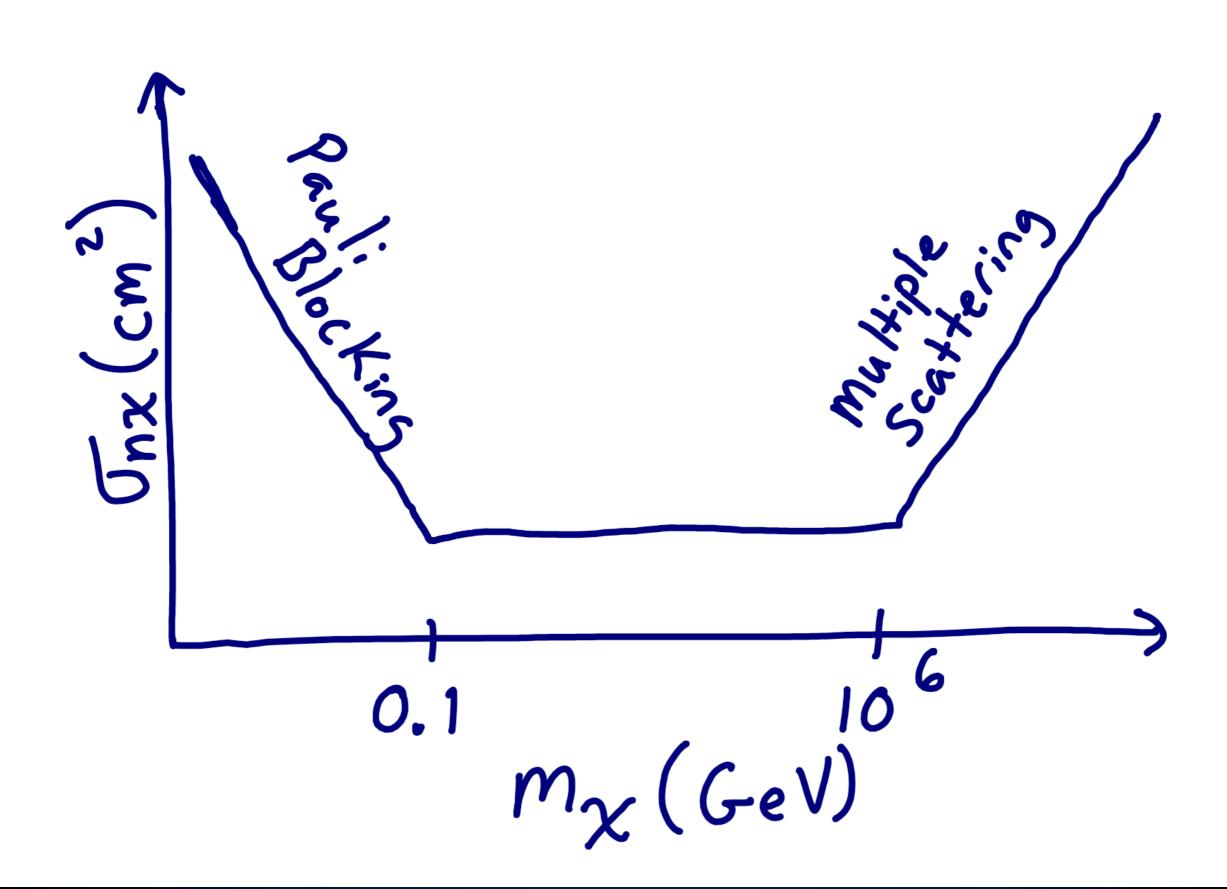

$$E_{loss} = \frac{2m_p}{m_\chi}(m_\chi v_\chi^2)$$

Very heavy dark matter requires multiple interactions:

$$\sigma_{\text{sat}}^{\text{multi}} \simeq 2 \times 10^{-45} \text{ cm}^2 \left(\frac{m_\text{x}}{\text{PeV}}\right)\left(\frac{1.5 \text{ M}_\odot}{M}\right)\left(\frac{R}{10 \text{ km}}\right)^2.$$
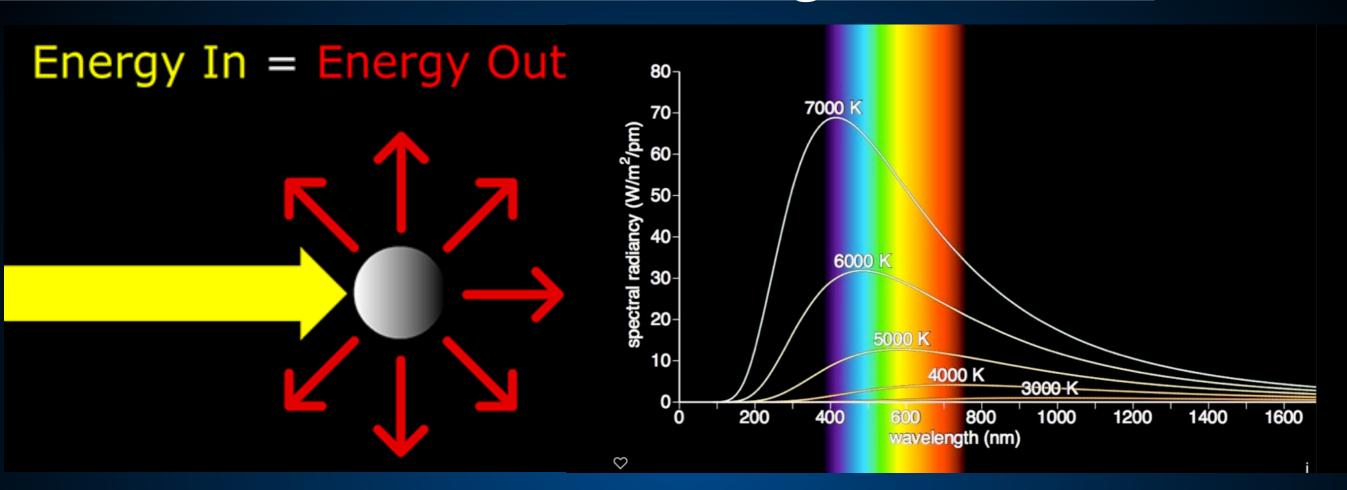

Detecting Dark Matter Scattering in Neutron Stars

Part I: Neutron Star Heating

Does the interaction produce an observable effect on the neutron star?

Dark Matter Induced Heating

DM-NS collisions impart significant energy into the NS:
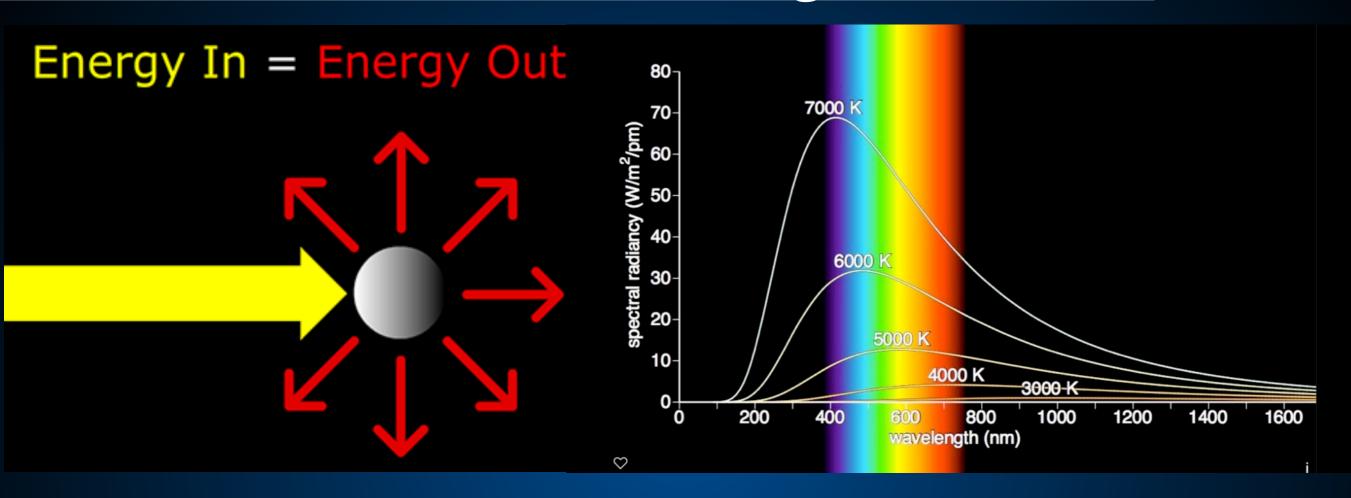

$$E_s \simeq m_x \left(\gamma - 1 \right)$$

This induces blackbody emission of luminosity:

$$\dot{E}_k = \frac{E_s \dot{m}}{m_x} f \simeq 1.4 \times 10^{25} \text{ GeV s}^{-1} \left(\frac{f}{1} \right),$$

Baryakhtar, Bramante, Li, TL, Raj (1704.01577)

Dark Matter Induced Heating

If Dark Matter subsequently annihilates, additional energy is injected **(de Lavellez & Fairbairn (1004.0629))**

$$E_{\text{s}} \simeq m_{\text{x}}\left(\gamma - 1\right)$$

Baryakhtar, Bramante, Li, TL, Raj (1704.01577)
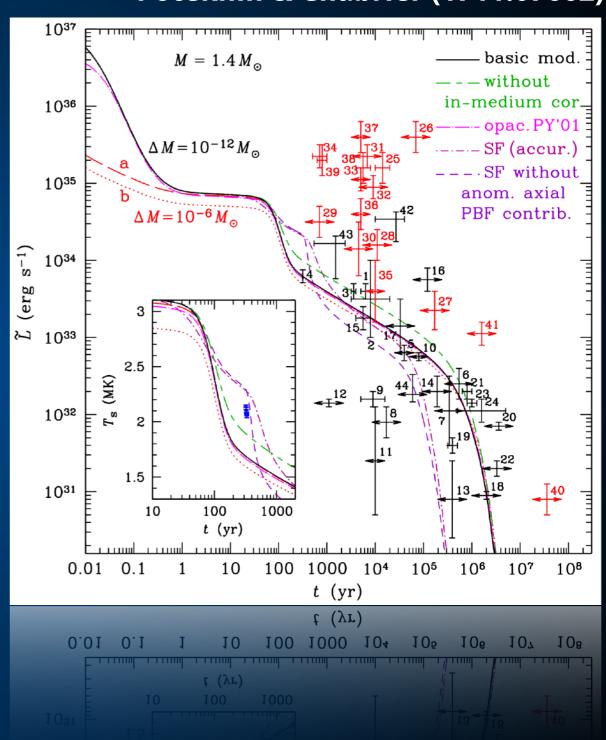

Detecting Hot Neutron Stars
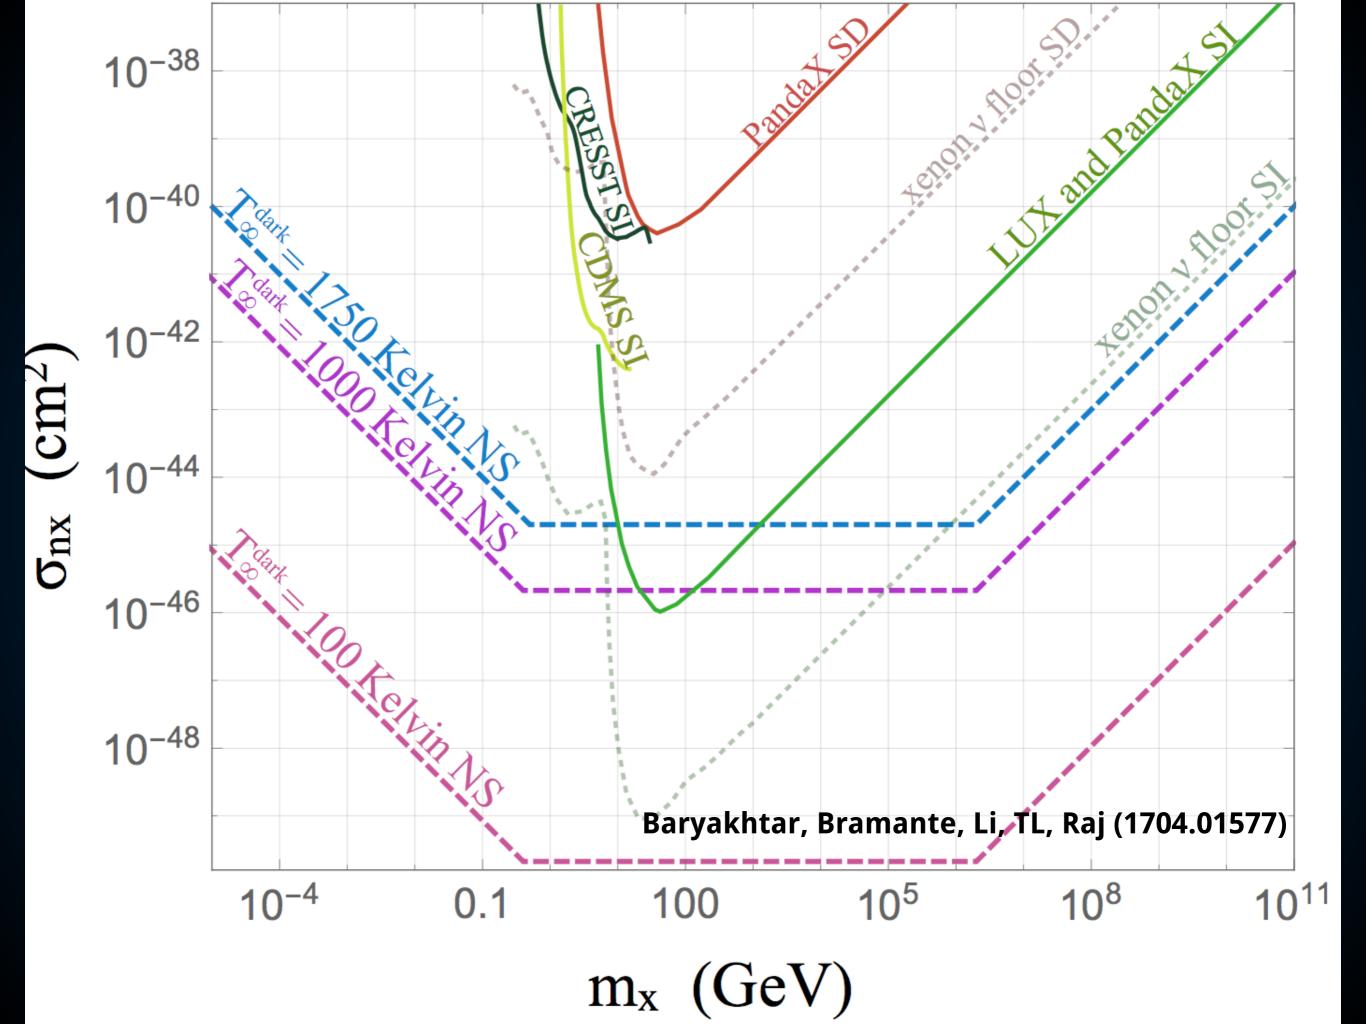

- **Thermal emission detected from young neutron stars**

- **Older neutron stars continue cooling**

- **Dark matter sets a minimum temperature of ~2000 K (10^{22} erg)**

Baryakhtar, Bramante, Li, TL, Raj (1704.01577)
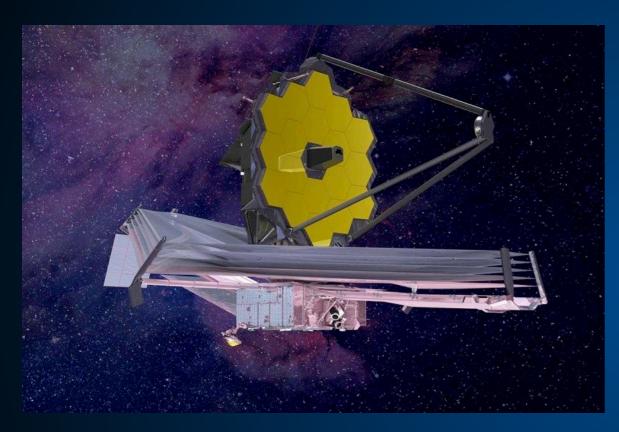

Detecting Thermal Emission

- **Observations at 2000 K require infrared telescopes**

JWST

10 nJy in 10^4 s

GMT

0.5 nJy in 10^5 s

- **A pulsar at 10 pc would have a flux of ~2 nJy at 2 microns**

Baryakhtar, Bramante, Li, TL, Raj (1704.01577)

What Do We Need?

1. **A nearby pulsar (10-20 pc).**

   - **Closest observed pulsar: 90 pc (PSR B1055-52)**

   - **Average Distance to nearest NS: 10 pc (Sartore et al. 0908.3182)**

2. **A model to separate thermal from pulsed emission**

3. **Constraints on thermal injection sources, e.g. gas accretion and magnetic heating.**

Detecting Dark Matter Scattering in Neutron Stars

Part II: Dark Matter Collapse

How does the interaction affect the dark matter?

The Secret Life of Dark Matter Inside a Neutron Star

- **Capture - DM hits neutron and elastically scatters**

- **Thermalization - Trapped dark matter thermalizes with neutron superfluid. If dark matter can annihilate, it will.**

- **Collapse - Dark matter degeneracy pressure not capable of preventing collapse.**

Bramante & TL (1405.1031)
Bramante & TL (1601.06784)
Bramante, TL, Tsai (1706.00001)

Dark Matter Thermalization

- **Dark Matter thermalization is always suppressed by Pauli blocking.**

- **Superfluidity and superconductivity effects in the NS core also have a sizable effect.**

- **However, if DM is trapped within the NS, interactions are inevitable. in pessimistic scenarios, DM thermalizes in a timeframe:**

$$t_{th} \simeq 3.7 \text{ kyr} \frac{\frac{m_X}{m_B}}{(1 + \frac{m_X}{m_B})^2} \left(\frac{2 \times 10^{-45} \text{ cm}^2}{\sigma_{nX}} \right) \left(\frac{10^5 \text{ K}}{T_{NS}} \right)^2$$

Dark Matter Collapse

▸ **Two paths are possible:**

▸ **If dark matter can annihilate,** the large densities make annihilation inevitable.

▸ **If dark matter cannot annihilate,** dark matter builds mass until it exceeds its own degeneracy pressure. For Fermionic dark matter this is:

$$M_{crit}^{ferm} \simeq M_{pl}^3 / m_X^2$$

▸ **It then collapses on a timescale:**

$$\tau_{co} \simeq \frac{1}{n\sigma_{nx}v_x} \left(\frac{p_F}{\Delta p}\right) \left(\frac{m_x}{2m_n}\right)$$

$$\simeq 4 \times 10^5 \text{ yrs} \left(\frac{10^{-45} \text{ cm}^2}{\sigma_{nx}}\right) \left(\frac{r_x}{r_0}\right),$$

Dark Matter Parameter Space

- **Requires dark matter to be non-annihilating.**

 - **PeV Fermionic Dark Matter**

$$M_{crit}^{ferm} \simeq M_{pl}^3 / m_X^2$$

  - **Bosonic Dark Matter**

  - **Attractive Self-Interacting Dark Matter**

- **Precise measurements are possible.**

One Slide on Axion Dark Matter

Axions proposed to solve the strong-CP problem
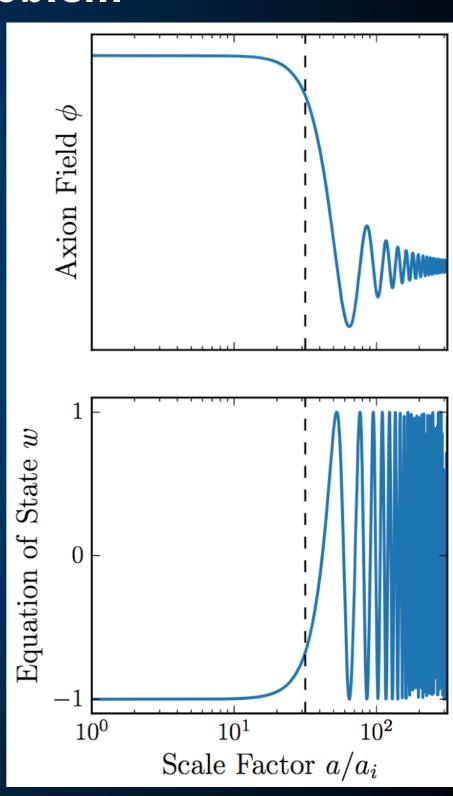

$$L_\theta = \theta \frac{g^2}{32\pi^2} F_a^{\mu\nu} \tilde{F}_{a\mu\nu}$$

If this constant is promoted to a field, its self-interactions drive it to 0:

$$\mathcal{L}_\Theta \to \mathcal{L}_a = \frac{1}{2}\left(\partial_\mu a\right)^2 - \frac{\alpha_s}{8\pi f_a}\, a\, G\tilde{G}$$

This term must couple to the EM field, allowing for decays to photons:
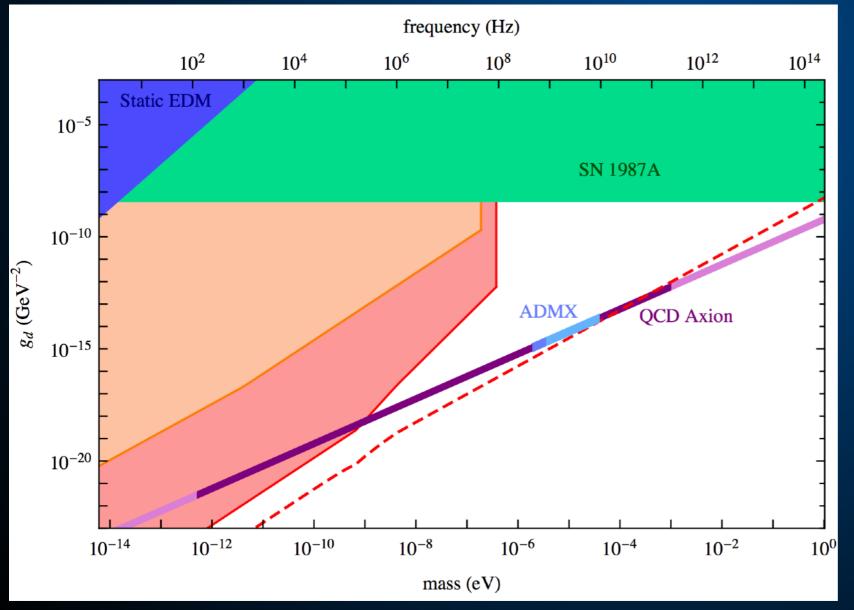

$$\mathcal{L}_{\text{int}} = -\frac{1}{4} g_{a\gamma} F_{\mu\nu} \tilde{F}^{\mu\nu} a = g_{a\gamma} \mathbf{E} \cdot \mathbf{B}\, a.$$

Marsh (2015; 1510.07633)

Detecting Axion Dark Matter

- **We can search for the resonant decay to photons:**

$$P_{\mathrm{SIG}} = \eta g_{a\gamma\gamma}^2 \left(\frac{\rho_a}{m_a} \right) B_0^2 V C Q_L$$

Neutron Stars: The Optimal Axion Laboratory

$$P_{a\gamma} \sim g_{a\gamma\gamma}^2 \mathbf{B}^2 L^2$$

Neutron Star

- 10^8 m²

10^{28} T² m²

ADMX

- 10 T
- 1 m²

100 T² m²
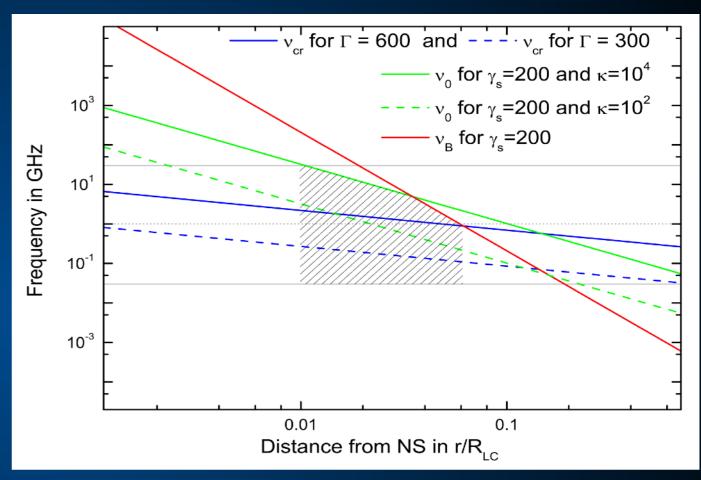

Neutron Stars: The Optimal Axion Laboratory

- **Resonant interactions occur when plasma frequency equals the axion mass:**

$$\omega_p \approx (1.5 \times 10^2 \text{ GHz}) \sqrt{\left(\frac{B_z}{10^{14} \text{ G}}\right)\left(\frac{1 \text{ sec}}{P}\right)}$$

= 6 x 10⁻⁴ eV
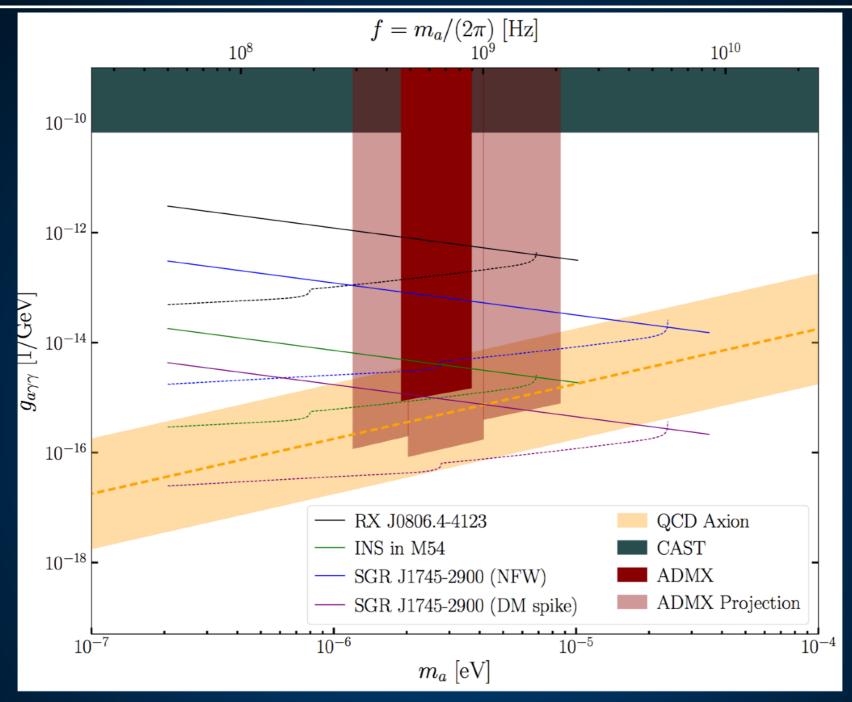

- **Need detailed model of NS magnetic fields.**

$$r_c(\theta, \theta_m, t) = 224 \text{ km} \times \left|3\cos\theta\,\hat{\mathbf{m}}\cdot\hat{\mathbf{r}} - \cos\theta_m\right|^{1/3} \times$$
$$\left(\frac{r_0}{10 \text{ km}}\right) \times \left[\frac{B_0}{10^{14} \text{ G}}\frac{1 \text{ sec}}{P}\left(\frac{1 \text{ GHz}}{m_a}\right)^2\right]^{1/3}.$$

Neutron Stars: The Optimal Axion Laboratory

- **Can place complementary constraints on the QCD axion.**

- **Specific to models where axions are the dark matter.**

Hook et al. (1804.03145)

What Do We Need?

1. Nearby, highly-magnetized pulsar.

2. Better models of the pulsar magnetic field.

3. Sensitive observations of radio lines (different techniques than traditional pulsar searches).

TL et al. (1703.09704)

Discovering Pulsars at TeV Energies

- **Tauris and Manchester (1998) calculated the beaming angle from a population of young an middle-aged pulsars.**

- **This varies between 15-30%.**

- **1/f pulsars are unseen in radio surveys.**
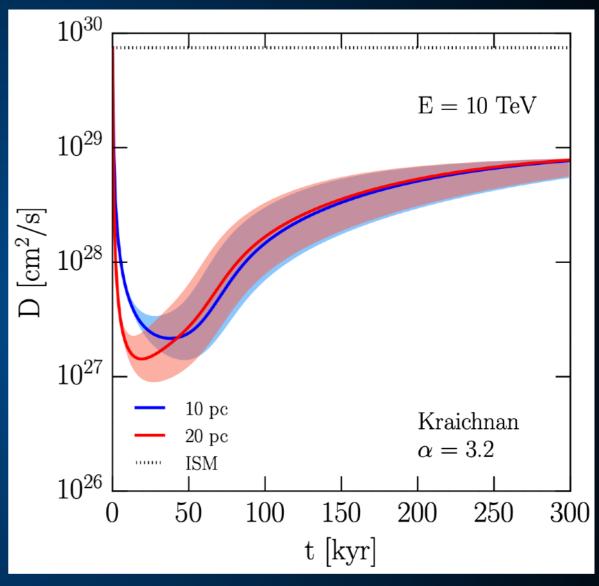

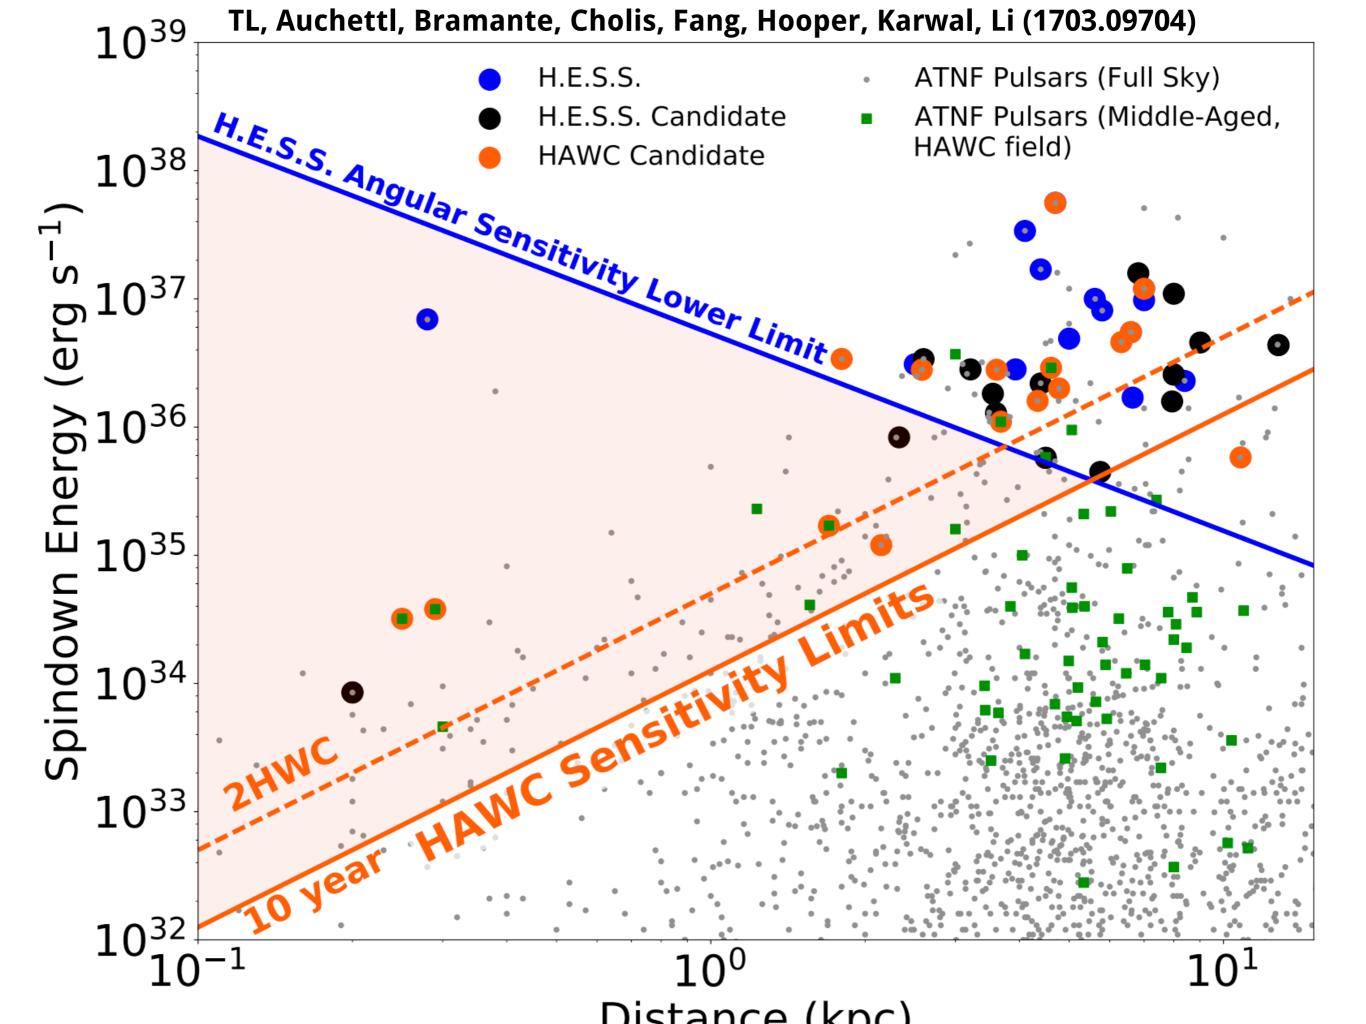

Discovering Pulsars at TeV Energies

- **Correcting for the beaming fraction implies that 56^{+15}_{-11} TeV halos are currently observed by HAWC.**

- **However, <u>only 39 HAWC sources</u> total.**

- **Chance overlaps, SNR contamination must be taken into account.**

What Do We Need?

1. **Continued observations of TeV halos.**

2. **A model for the confinement and emission of electrons in TeV halos.**

3. **A method for precisely determining the pulsar position within the TeV halo.**

TL, Auchettl, Bramante, Cholis, Fang, Hooper, Karwal, Li (1703.09704)

The Program

1. **Understand Dark Matter/Neutron Star Interactions**

   - **Can already set strong constraints on some models**

      1. **Asymmetric Dark Matter**

      2. **Axions**

   - **Can probe extremely generic dark matter models.**

The Program

1. **Understand Dark Matter/Neutron Star Interactions**

   - **Can already set strong constraints on some models**

     1. **Asymmetric Dark Matter**

     2. **Axions**

   - **Can probe extremely generic dark matter models.**

2. **Differentiate dim dark matter signals from astrophysics**

   - **Need detailed models of neutron star physics.**

   - **Requires observations of pulsars with "special" attributes**

     1. **Nearby**

     2. **Strong Magnetic Fields**

     3. **Not Beamed Towards Earth**

Conclusions

- **Pulsars have unique characteristics that are optimally suited for new physics searches.**

- **Early studies can set strong constraints on the asymmetric dark matter and axion parameter spaces.**

- **Our observational techniques are in their infancy. The next decade will revolutionize the field in several directions.**

Closing date: 01/12/2019

Postdoctoral Fellow in Astroparticle or Theoretical Particle Physics

at the Department of Physics. Closing date: 1 December 2019.

The Department of Physics is one of the biggest departments within the Faculty of Science and supports a broad range of basic research in experimental and theoretical physics. It has about 250 employees of which 95 are PhD students. Many have been internationally recruited. The Department is part of the AlbaNova University Center, which apart from the Department of Physics houses the Department of Astronomy, the Physics Departments at the Royal Institute of Technology (KTH), and the Nordic Institute for Theoretical Physics (Nordita).
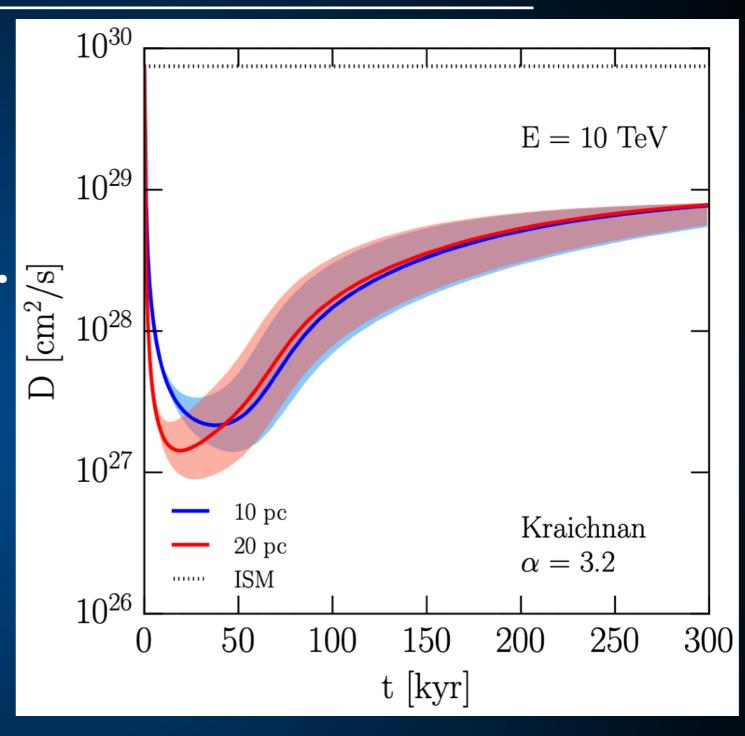

Project description
A current focus of this group is the confrontation of theoretical models from fundamental physics with astronomical observations. This specifically includes searches for astronomical dark matter signals; theoretical particle physics modeling; high-energy astrophysics; theoretical, experimental and observational aspects of axions; and theoretical cosmology of the early and late universe. The postdoctoral fellow will be a member of Frank Wilczek's group, and will have significant freedom to collaborate extensively with researchers situated across the Albanova campus.

The successful candidate will also be part of the Oskar Klein Centre for Cosmoparticle Physics (OKC; www.okc.albanova.se) in Stockholm, a rich scientific environment that comprises more than a hundred researchers working in both theory and experiment in the fields of astronomy, astrophysics and particle physics at both Stockholm University and the Royal Institute for Technology (KTH). The OKC hosts a vibrant research programme on dark matter, dark energy, transient and multimessenger astrophysics, structure formation, and related particle physics questions. Postdoctoral fellows are also welcome to participate in Scientific Programs at the

A Model for TeV Halos

- **Early results indicate that pulsars themselves can confine electrons to produce TeV halo emission.**

- **Analog with cosmic-ray confinement in supernova remnants.**

- **More detailed models including reacceleration and joint supernova/pulsar emission are necessary.**

Discovering Pulsars at TeV Energies

- **Tentative Evidence that MSPs also produce these TeV halos.**
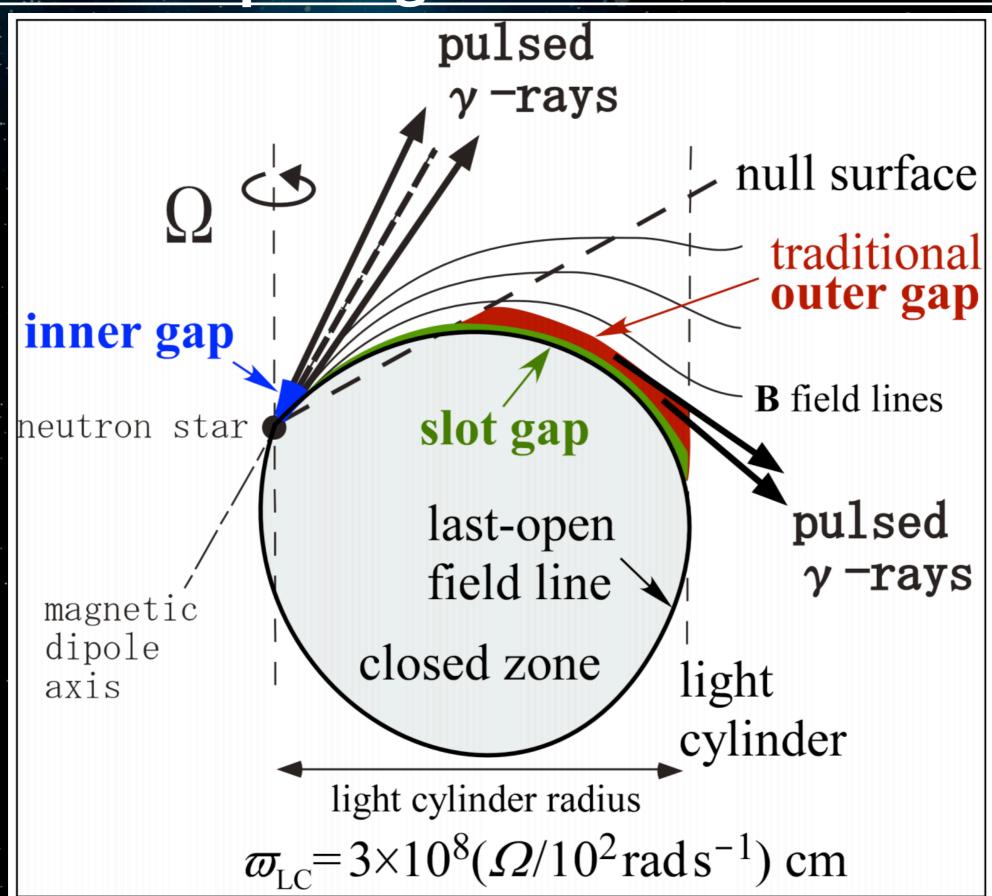

- **MSPs are the coldest and oldest pulsars – important for DM heating.**

- **Models indicate a MSP should exist within ~50 pc, but none has yet been found.**

Hooper & TL (1803.08046)

Dark Matter Thermalization

- **Dark Matter thermalization is always suppressed by Pauli blocking.**

- **Superfluidity and superconductivity effects in the NS core also have a sizable effect.**

- **However, if DM is trapped within the NS, interactions are inevitable. in pessimistic scenarios, DM thermalizes in a timeframe:**

$$t_{th} \simeq 3.7 \text{ kyr} \frac{\frac{m_X}{m_B}}{(1 + \frac{m_X}{m_B})^2} \left(\frac{2 \times 10^{-45} \text{ cm}^2}{\sigma_{nX}} \right) \left(\frac{10^5 \text{ K}}{T_{NS}} \right)^2$$
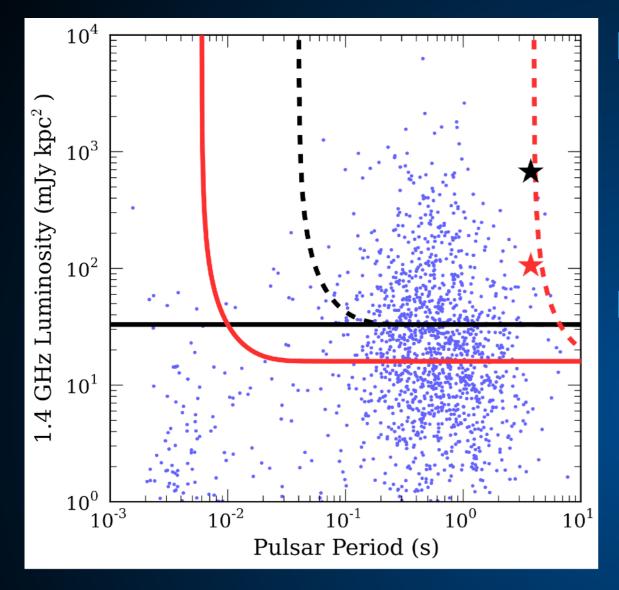

Dark Matter Collapse

▸ **Two paths are possible:**

  ▸ **If dark matter can annihilate, the large densities make annihilation inevitable.**

  ▸ **If dark matter cannot annihilate, dark matter builds mass until it exceeds its own degeneracy pressure. For Fermionic dark matter this is:**

$$M_{crit}^{ferm} \simeq M_{pl}^3 / m_X^2$$

  ▸ **It then collapses on a timescale:**

$$\tau_{\mathrm{co}} \simeq \frac{1}{n \sigma_{nx} v_{\mathrm{x}}} \left(\frac{p_F}{\Delta p} \right) \left(\frac{m_{\mathrm{x}}}{2 m_n} \right)$$

$$\simeq 4 \times 10^5 \text{ yrs} \left(\frac{10^{-45} \text{ cm}^2}{\sigma_{\mathrm{nx}}} \right) \left(\frac{r_x}{r_0} \right),$$

The Missing Pulsar Problem

- **Large pulse dispersion was reasonable culprit**

$$\Delta\tau \sim 1\ \text{s} \left(\frac{\text{Ghz}}{\nu}\right)^4$$

- **Magnetar found in X-Ray observations in 2013.**

  - **No pulse dispersion in X-Rays**

- **Magnetar subsequently found in radio**

- **Pulse dispersion is small!**
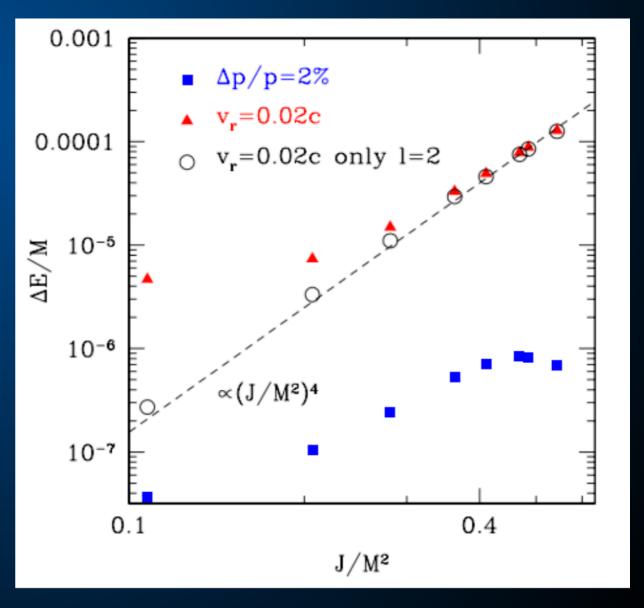

- **Why aren't any other pulsars observed !?**

Gravitational Waves from NS Collapse

▸ **Gravitational Waves from DM induced collapse**

$$h_c \sim 5 \times 10^{-22} \left(\frac{M}{M_\odot} \right) \left(\frac{10 \text{ kpc}}{D} \right) \; @ \; 531 \text{ Hz,}$$
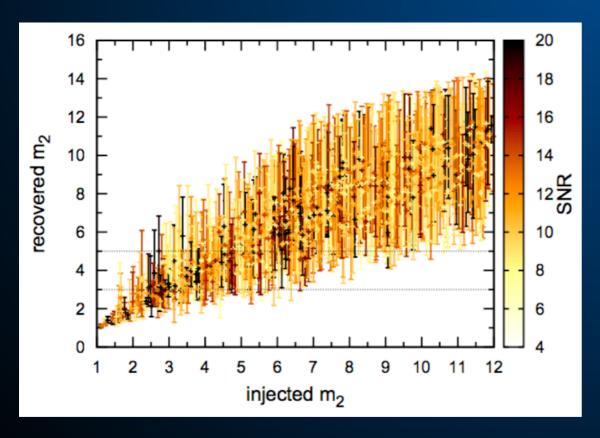

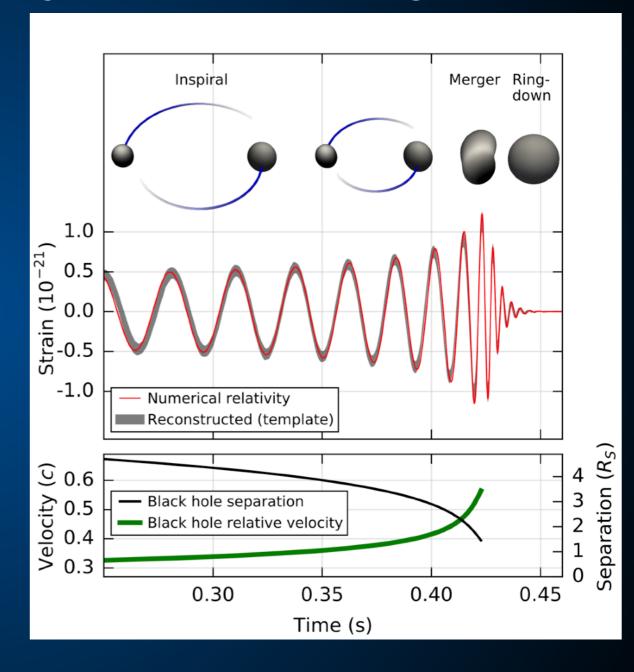

Baiotti et al. (gr-qc/0701043)

▸ **Single NS collapse models have been considered (primarily from accretion induced collapse).**

▸ **DM induced NS collapse observable throughout the Milky Way (0.01 yr^{-1} ?)**
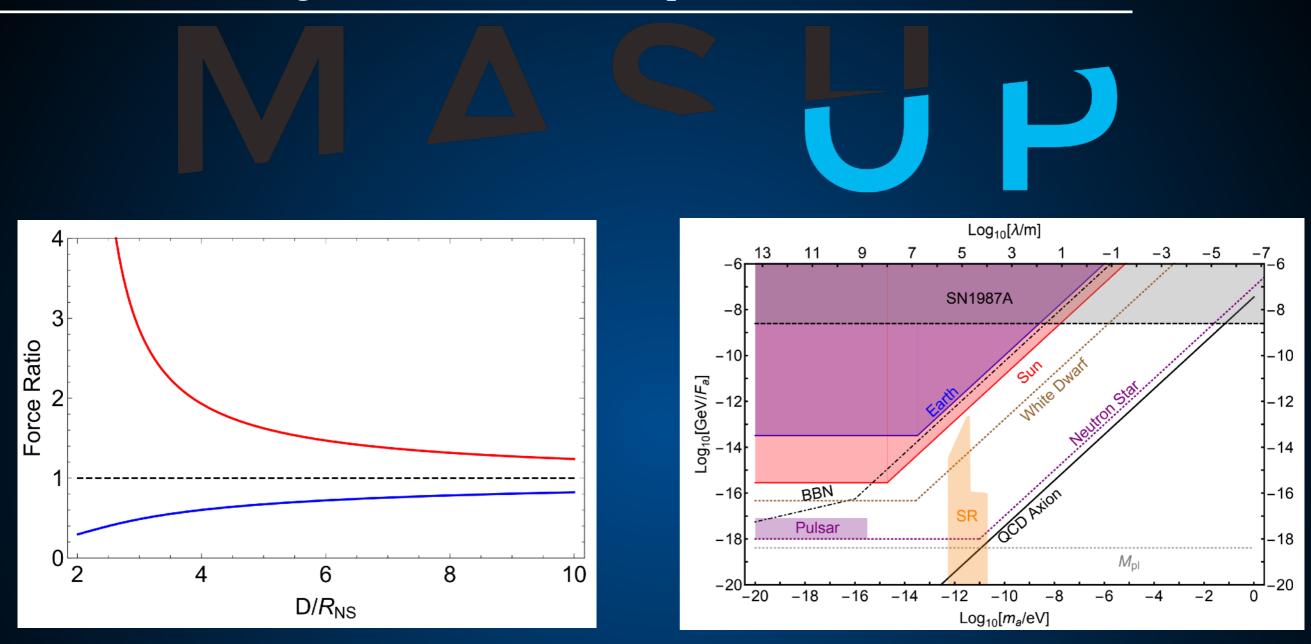

Differentiating Black Hole and NS Mergers

▸ **Anomalies in the tidal strain of binary neutron star mergers.**

- ▸ **DM induced NS collapse produces a population of 1.4 M_o black holes.**

- ▸ **Can potentially see differences in merger and ring-down, but not presently feasible.**

One More Slide on Axion Dark Matter

Axions proposed to solve the strong-CP problem

$$L_\theta = \theta \frac{g^2}{32\pi^2} F_a^{\mu\nu} \tilde{F}_{a\mu\nu}$$

This is the sum of two different terms, that independently must be small.

$$\left| \Theta_{\text{QCD}} + \arg \det M_q \right| \lesssim 10^{-9}$$

This provides you with an independent way to solve the strong-CP problem - by setting m_u = 0.

However, this appears to be at odds with experimental data.

QCD Axion Mass Bounds

QCD Axion obtains its mass from its decay constant and the coupling to quarks:
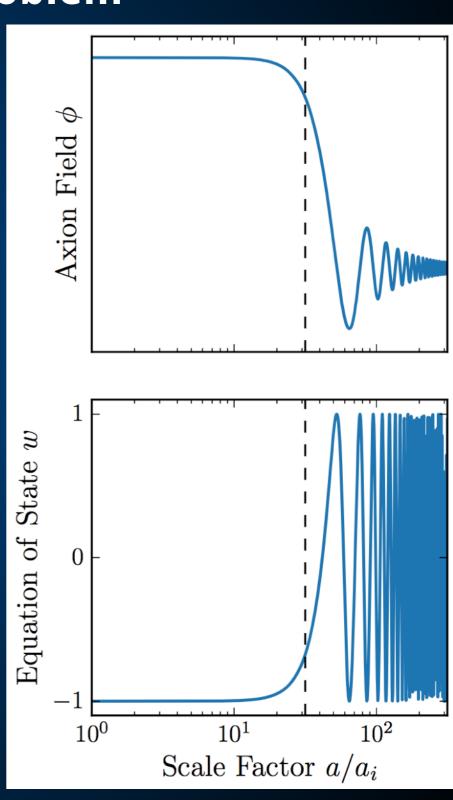

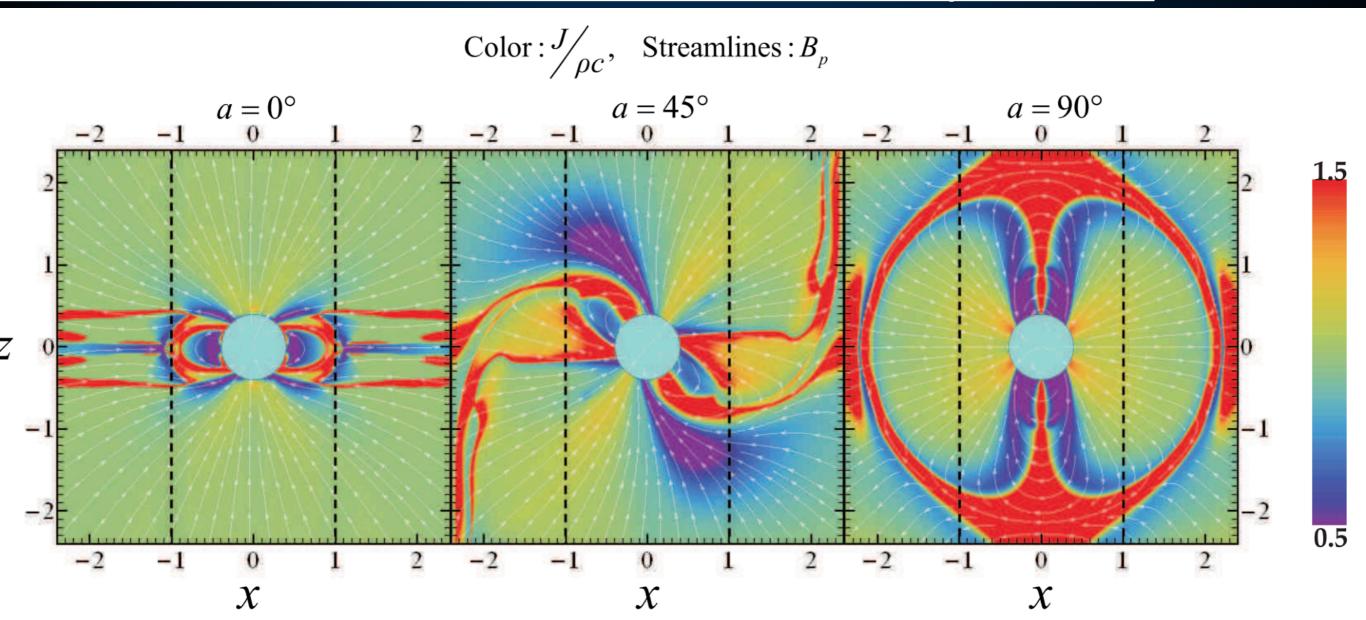

$$m_a = \frac{f_\pi m_\pi}{f_a} \left(\frac{z}{(1+z+w)(1+z)} \right)^{1/2}$$
$$= 0.60 \, \text{eV} \, \frac{10^7 \, \text{GeV}}{f_a},$$

The high-mass range of the QCD axion (low-f_a) is set by the constraint that the axion never comes into thermal equilibrium (and light-through a wall and astrophysical constraints).

The low mass (high-fa) limit is set such that axions don't overclose the universe:

$$\Omega_a h^2 \approx 0.23 \times 10^{\pm 0.6} (f_a / 10^{12} \, \text{GeV})^{1.175} \, \Theta_i^2 \, F(\Theta_i)$$

Raffelt 1995

Goldreich-Julian Current

Color : $J/\rho c$,   Streamlines : B_p

$a = 0°$ $a = 45°$ $a = 90°$

NS is a conductor with a strong rotating magnetic field. Thus, an electric field and current are formed.

**In these simulations the NS is not a perfect dipole.**

A Signal

10% of Star Formation in central 200 pc of Milky Way

Massive Star Formation in the Galactic Center

By Don F. Figer
Rochester Institute of Technology, Rochester, NY, USA

The Galactic center is a hotbed of star formation activity, containing the most massive star formation site and three of the most massive young star clusters in the Galaxy. Given such a rich environment, it contains more stars with initial masses above 100 $M_\odot$ than anywhere else in the Galaxy. This review concerns the young stellar population in the region. The sample includes stars in the three massive stellar clusters, the population of younger stars in the present sites of star formation, the stars surrounding the central black hole, and the bulk of the stars in the field population. The fossil record in the Galactic center suggests that the recently formed massive stars are present-day examples of similar populations that must have been formed through the numerous episodes stretching back to the time period when the Galaxy was forming.

Dark Matter Induced Collapse in dSphs

- **The dispersion velocity in dwarfs is also small.**

    - **Reticulum II: 3.3 +/- 0.7 km s⁻¹ (Simon et al. 2015)**

- **Dark matter accumulation rate scales inversely with velocity:**
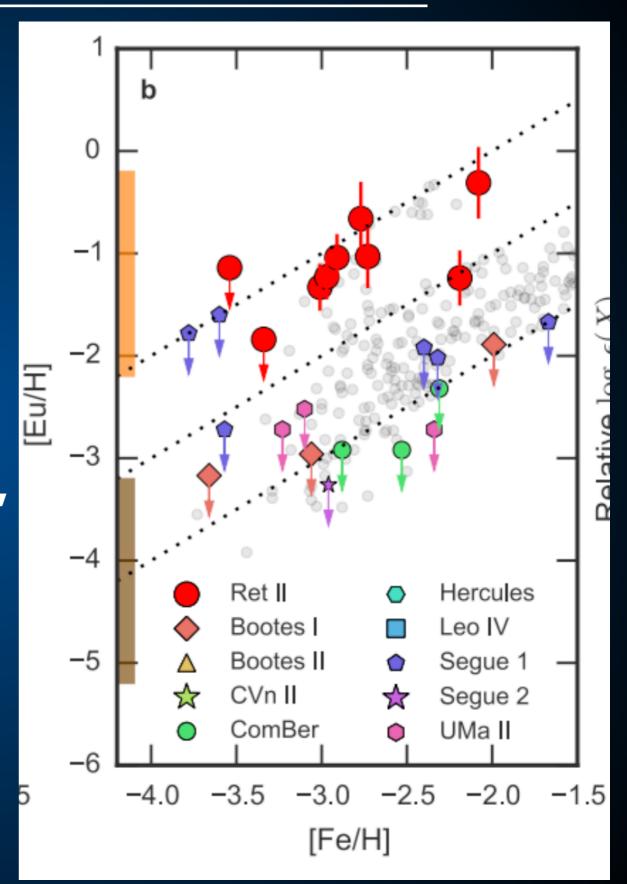

$$\dot{m}_{\mathrm{x}} = \pi \rho_{\mathrm{x}} \frac{2GMR}{v_{\mathrm{x}}} \left(1 - \frac{2GM}{R} \right)^{-1}$$
$$\simeq \frac{10^{26} \text{ GeV}}{\text{s}} \left(\frac{\rho_{\mathrm{x}}}{\text{GeV/cm}^3} \right) \left(\frac{200 \text{ km/s}}{v_{\mathrm{x}}} \right),$$
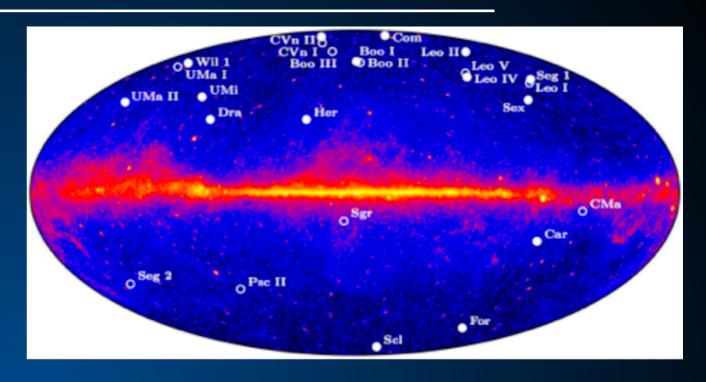

- **Dwarf Spheroidal Galaxies are an optimal laboratory for asymmetric dark matter detection.**

Dark Matter Induced Collapse in dSphs

- **Reticulum II dSph**

  - **Discovered by DES in 2015**

  - **Spectroscopic follow-up determined r-process abundances.**
  - **Large r-process abundance, but low metallicity!**

- **Points to a rare formation channel (NS mergers)**

Dark Matter Induced Collapse in dSphs

- **Normalize the nuclear cross-section to the missing pulsar problem.**

- **Supernovae produce ~100 events.**

- **Mergers produce ~0.0005 events**

- **DM induced collapse produces ~0.1-3 events.**
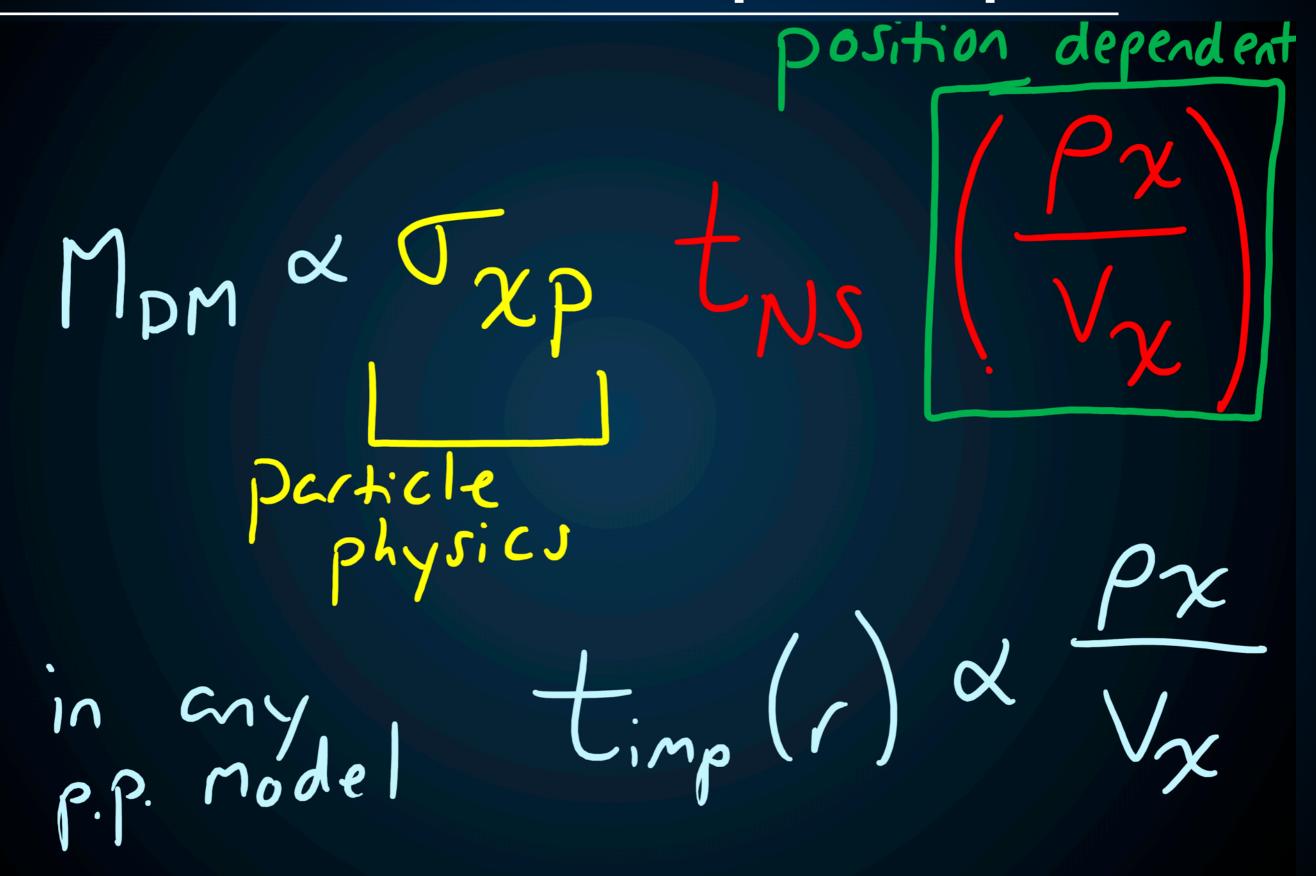

Dark Matter Induced Collapse in dSphs

- **Prediction: Globular Clusters should not be similarly r-process enriched.**

- **In fact, no globular cluster has been observed to have an r-process overabundance exceeding 1.2 dex.**

- **6 of 9 stars in Reticulum II have r-process enrichment exceeding 1.68 dex.**

Dark Matter Induced Collapse in dSphs

$$M_{DM} \propto \sigma_{\chi p} \; t_{NS} \left(\frac{\rho_\chi}{v_\chi} \right)$$

particle physics

in any P.P. model

$$t_{imp}(r) \propto \frac{\rho_\chi}{v_\chi}$$

Pulsars Produce the Positron Excess

- **Can calculate the gamma-ray spectrum necessary to fit the Geminga data from HAWC and Milagro**

- **Can use this to calculate the underlying steady-state electron and positron spectrum**

Hooper, Cholis, TL, Fang (1702.08436)

Pulsars Produce the Positron Excess

- **Utilizing a diffusion model, along with the steady state electron spectrum, and the morphology of the emission, can calculate the fraction of the electron energy lost before escaping the halo.**
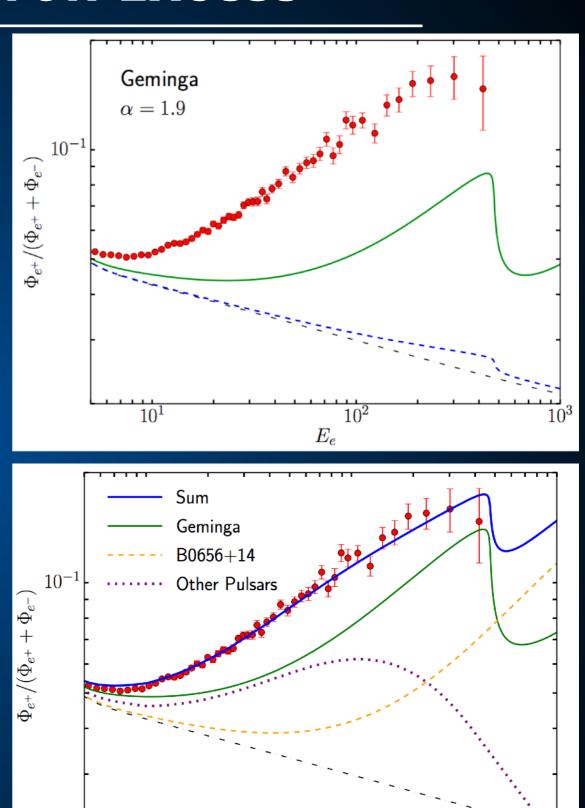

- **Less energetic electrons make it to the ISM!**

Hooper, Cholis, TL, Fang (1702.08436)

Pulsars Produce the Positron Excess

- **In these models, Geminga naturally produces ~50% of the positron excess.**

- **The total contribution from the remaining Milky Way pulsars produces the remaining emission.**
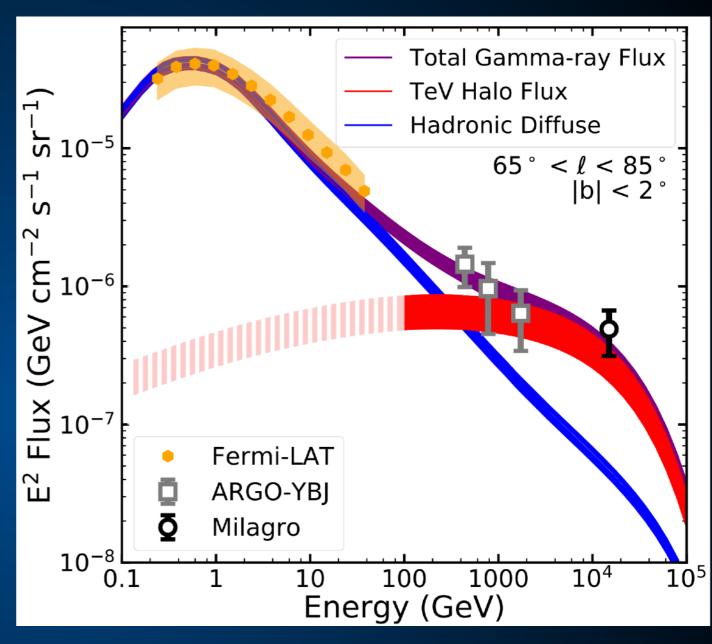

- **Difficult to understand TeV halo spectrum if pulsars <u>do not</u> make the positron excess.**

Hooper, Cholis, TL, Fang (1702.08436)

Pulsars Produce the TeV Excess

- **Milagro detected bright diffuse TeV emission along the Galactic plane.**

- **The intensity of this emission is incompatible with hadronic models constrained by Fermi and Argo-YBJ data.**

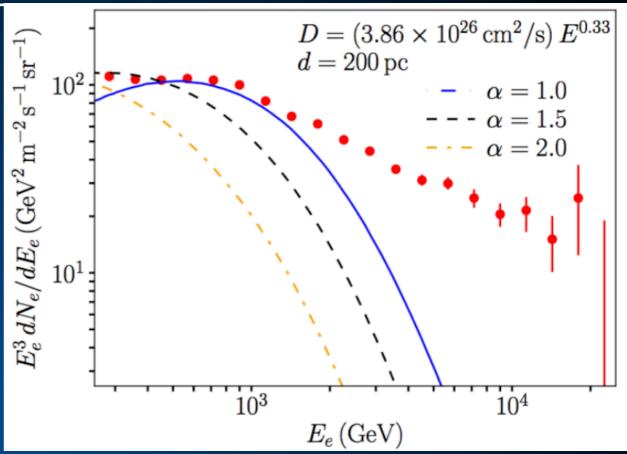

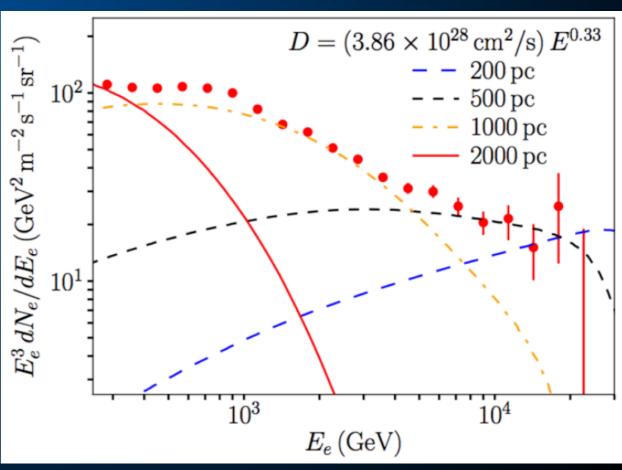

TL & Buckman (1707.01905)

- **TeV halos produce a hard spectrum component that naturally explains the intensity and spectrum of this emission.**

Pulsars Produce Anisotropic Diffusion

- **Diffusion near TeV halo is known to be suppressed - by two orders of magnitude!**

- **Diffusion constant near us must be high to explain observations of 10 TeV electrons.**

- **Pulsars produce regions of low-diffusion, where TeV halos shine!**

Hooper & TL (1711.07482)

# Pulsars Produce Anisotropic Diffusion

- **Cosmic-Ray electrons produced by the pulsar obtain a steep gradient.**

- **This excites Alfven waves moving parallel to the electron gradient.**

$$\Gamma_{CR}(k) = \frac{2\pi}{3} \frac{c|v_A|}{k\mathcal{W}(k)U_0} \left[p^4 \frac{\partial f}{\partial z} \right]_{p_{res}}$$

- **These Alfven waves dominate cosmic-ray turbulence, because they are resonant with the electron energy - leads to low diffusion**

Evoli, TL & Morlino (TBS)

Pulsars Produce Galactic Center Pevatron

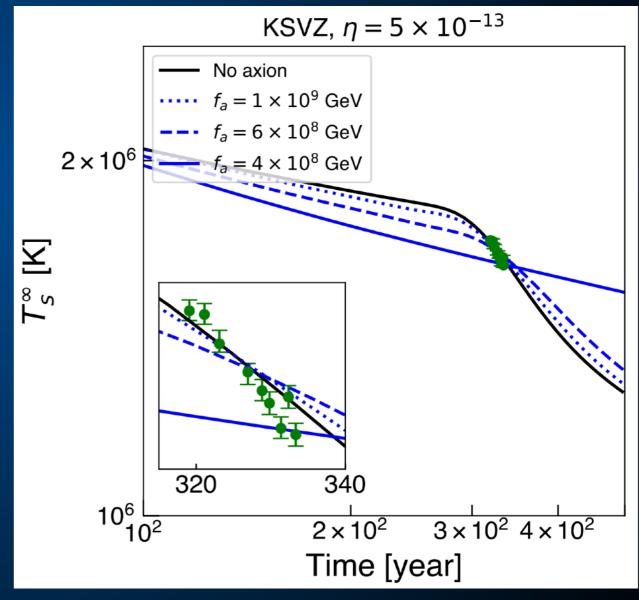

- **The spectrum of the HESS pevatron looks like the Geminga spectrum.**

- **Diffuse electrons can be made via pulsar natal kicks.**

Hooper, Cholis, TL (1705.09293)

Particle Physics Mash-Up

- **Can also use neutron star cooling curves to place limits on the axion cross-section.**

- **Observations of the Cassiopeia A NS, with a known age of 337 years, rule out $f_a < 5 \times 10^8$ GeV.**

Hamaguchi et al. (1806.07151)
