CENTER FOR COSMOLOGY AND ASTROPARTICLE PHYSICS

TeV Flux ~ 3 x 10³³ TeV s⁻¹ > 10% of Spindown Power!

Powered by inverse Compton scattering of accelerated electrons

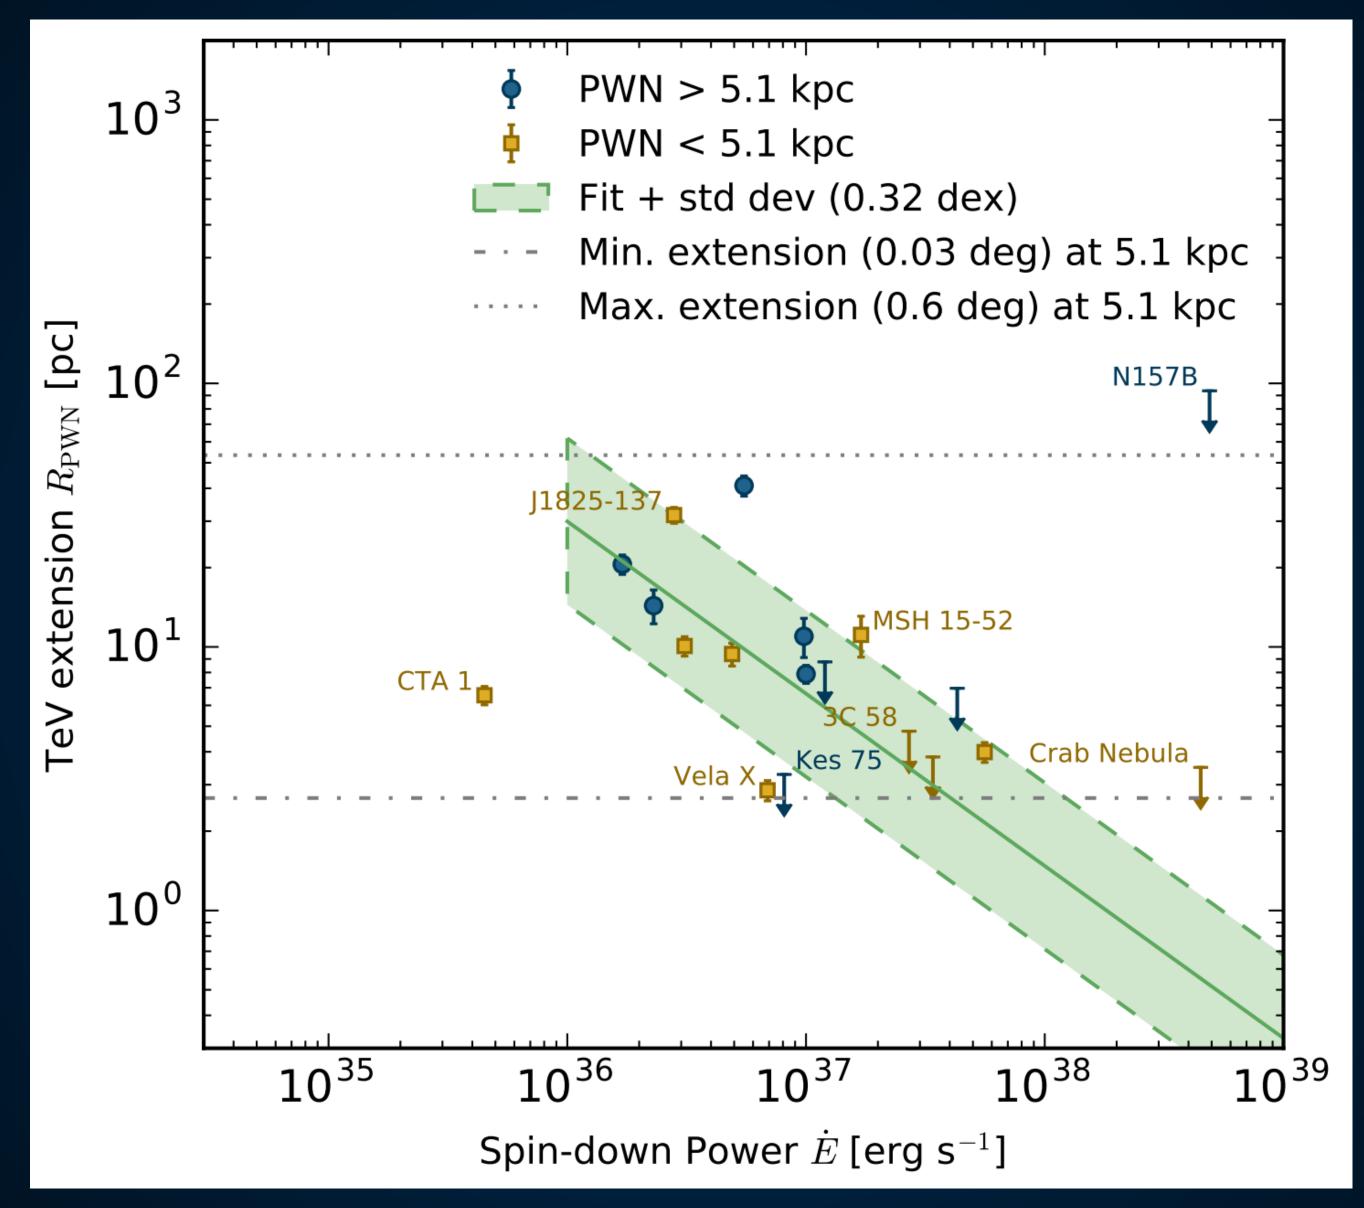

Geminga

Extended to 5° (20 pc)!

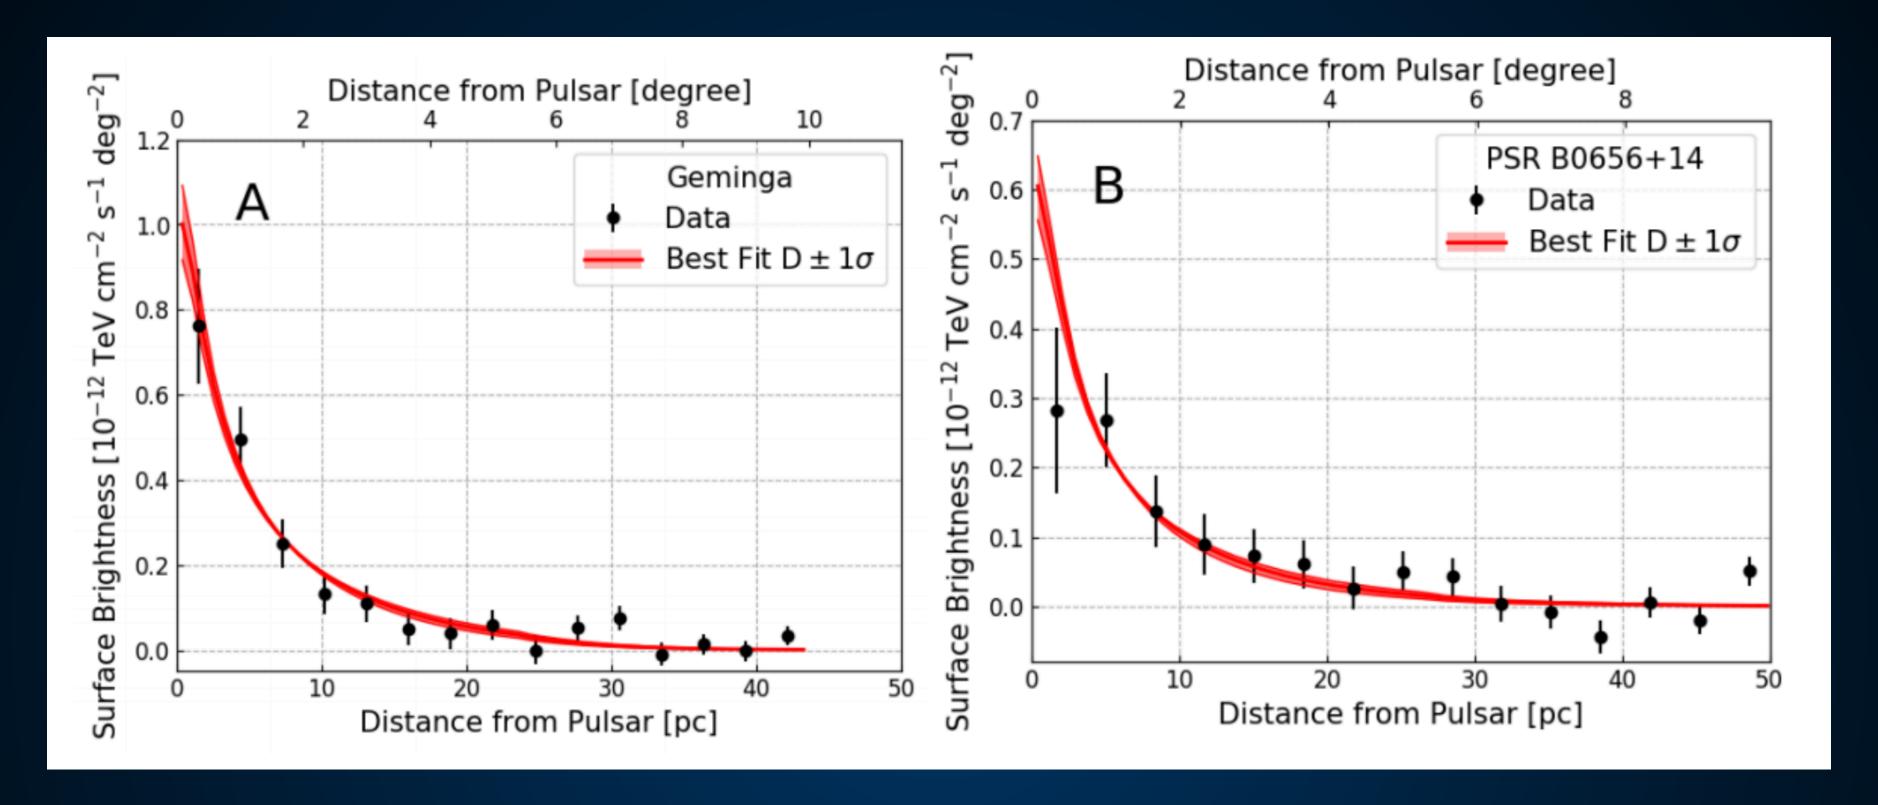

I will call these objects TeV halos

PSR B0656+14

2HWC Catalog (1702.02992)
HAWC Collaboration (1711.06223)

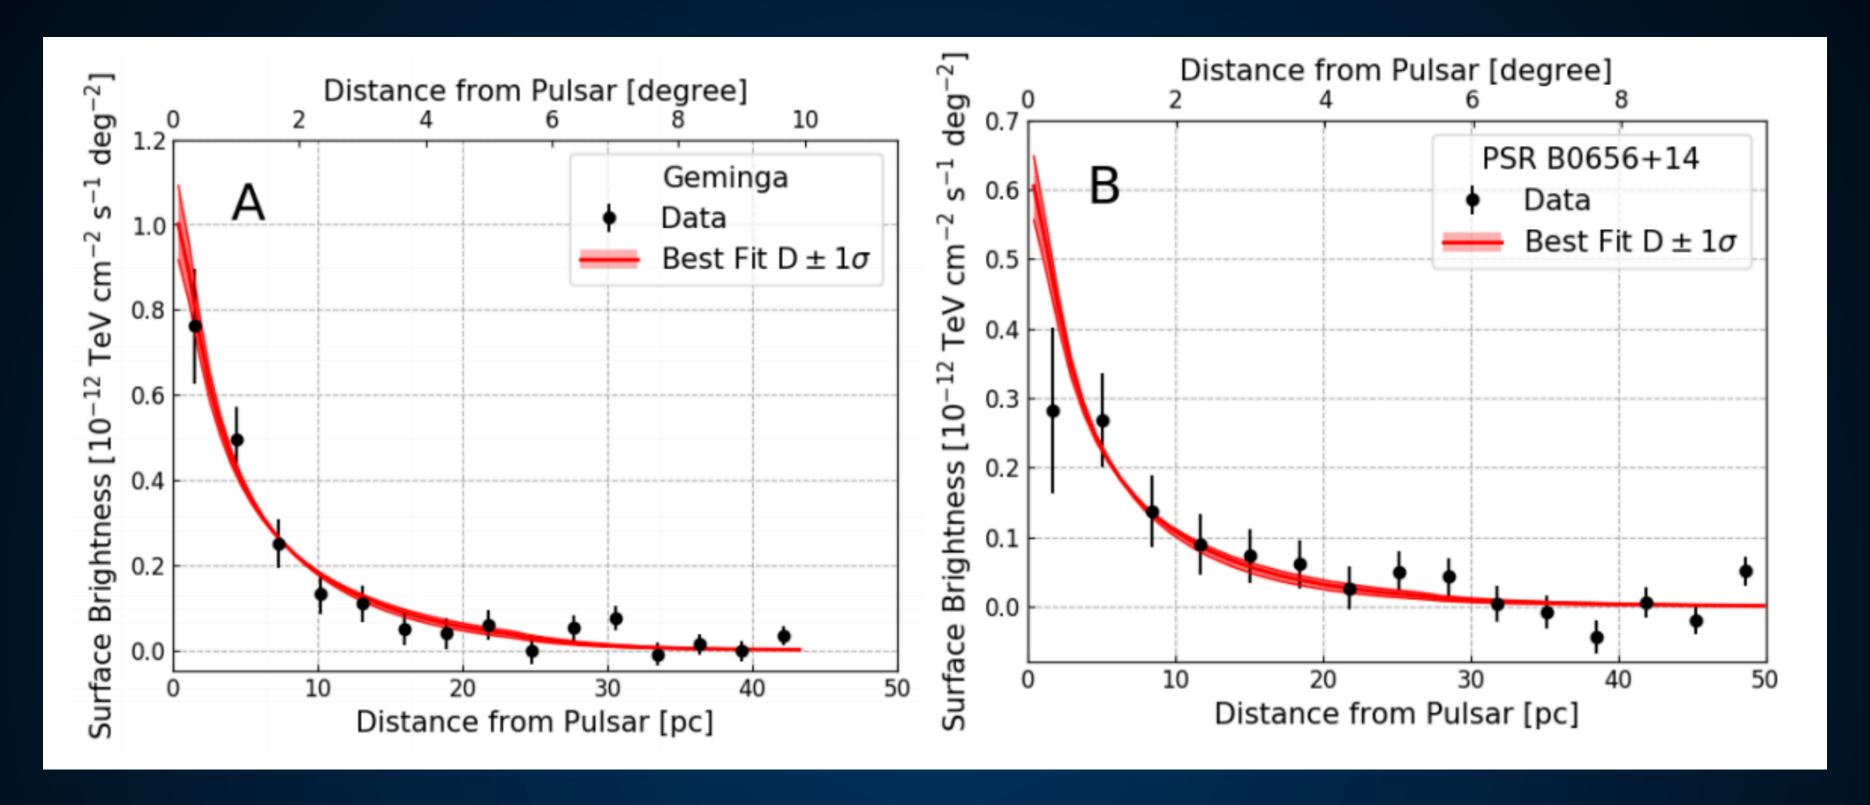

"TeV PWN" observed by HESS have similar fluxes and extensions.

- Why TeV Halos?
 - These sources are much larger than X-Ray PWN

$$R_{\rm PWN} \simeq 1.5 \left(\frac{\dot{E}}{10^{35} \, {\rm erg/s}}\right)^{1/2} \times \\ \left(\frac{n_{\rm gas}}{1 \, {\rm cm}^{-3}}\right)^{-1/2} \left(\frac{v}{100 \, {\rm km/s}}\right)^{-3/2} {\rm pc}$$

Why TeV Halos?

These sources are much smaller than diffusion through the ISM

$$T_{loss} \approx 30 \text{ Kyr} \quad D_o \approx 5 \times 10^{28} \text{ cm}^2 \text{ s}^{-1}$$

$$L = \sqrt{Dt} \approx 2000 \text{ pc}$$

a new morphology requires a new physical mechanism

The Global Population of TeV Halos

Make One Key Assumption:

The following correlation is consistent with the data.

$$\phi_{\text{TeV halo}} = \left(\frac{\dot{E}_{\text{psr}}}{\dot{E}_{\text{Geminga}}}\right) \left(\frac{d_{\text{Geminga}}^2}{d_{\text{psr}}^2}\right) \phi_{\text{Geminga}}$$

Note: Using Monogem would increases fluxes by nearly a factor of 2. The power law of this correlation doesn't greatly affect the results.

HAWC Observations of TeV Halo Luminosities

Linden et al. (PRD; 1703.09704)

HAWC detection of TeV emission near PSR B0540+23

ATel #10941; Colas Riviere (University of Maryland), Henrike Fleischhack (Michigan Technological University), Andres Sandoval (Universidad Nacional Autonoma de Mexico) on behalf of the HAWC collaboration

on 9 Nov 2017; 23:11 UT
Credential Certification: Colas Riviere (riviere@umd.edu)

Subjects: Gamma Ray, TeV, VHE, Pulsar

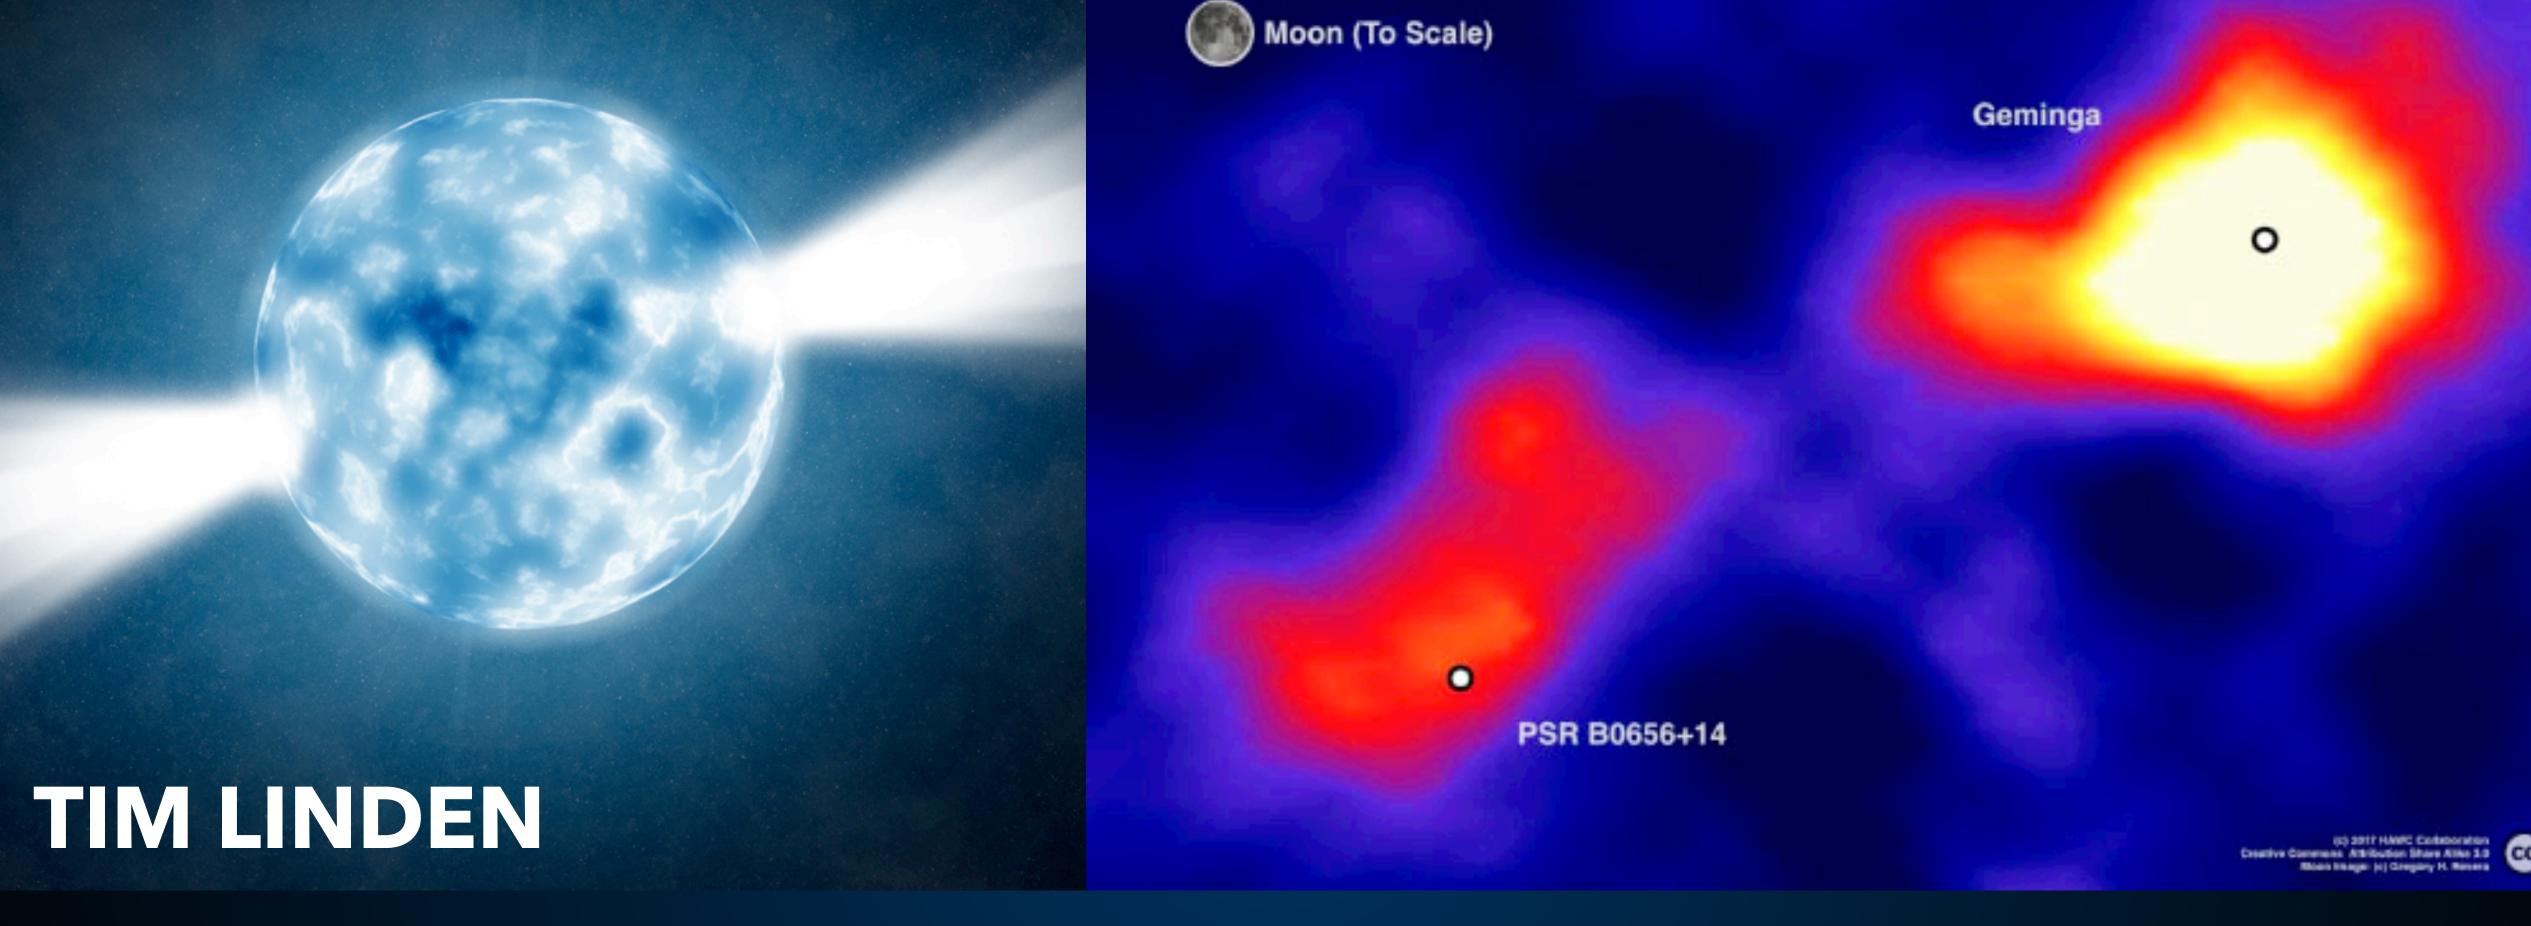

The High Altitude Water Cherenkov (HAWC) collaboration reports the discovery of a new TeV gamma-ray source HAWC J0543+233. It was discovered in a search for extended sources of radius 0.5° in a dataset of 911 days (ranging from November 2014 to August 2017) with a test statistic value of 36 (6 σ pre-trials), following the method presented in Abeysekara et al. 2017, ApJ, 843, 40. The measured J2000.0 equatorial position is RA=85.78°, Dec=23.40° with a statistical uncertainty of 0.2°. HAWC J0543+233 was close to passing the selection criteria of the 2HWC catalog (Abeysekara et al. 2017, ApJ, 843, 40, see HAWC J0543+233 in 2HWC map), which it now fulfills with the additional data.

HAWC J0543+233 is positionally coincident with the pulsar PSR B0540+23 (Edot = 4.1e+34 erg s-1, dist = 1.56 kpc, age = 253 kyr). It is the third low Edot, middle-aged pulsar announced to be detected with a TeV halo, along with Geminga and B0656+14. It was predicted to be one of the next such detection by HAWC by Linden et al., 2017, arXiv:1703.09704.

Using a simple source model consisting of a disk of radius 0.5° , the measured spectral index is -2.3 ± 0.2 and the differential flux at 7 TeV is $(7.9 \pm 2.3) \times 10^{\circ}-15$ TeV-1 cm-2 s-1. The errors are statistical only. Further morphological and spectral analysis as well as studies of the systematic uncertainty are ongoing.

Tauris and Manchester (1998) calculated the beaming angle from a population of young and middle-aged pulsars.

$$f = \left[1.1 \left(\log_{10} \left(\frac{\tau}{100 \text{ Myr}}\right)\right)^2 + 15\right] \%$$

This varies between 15-30%.

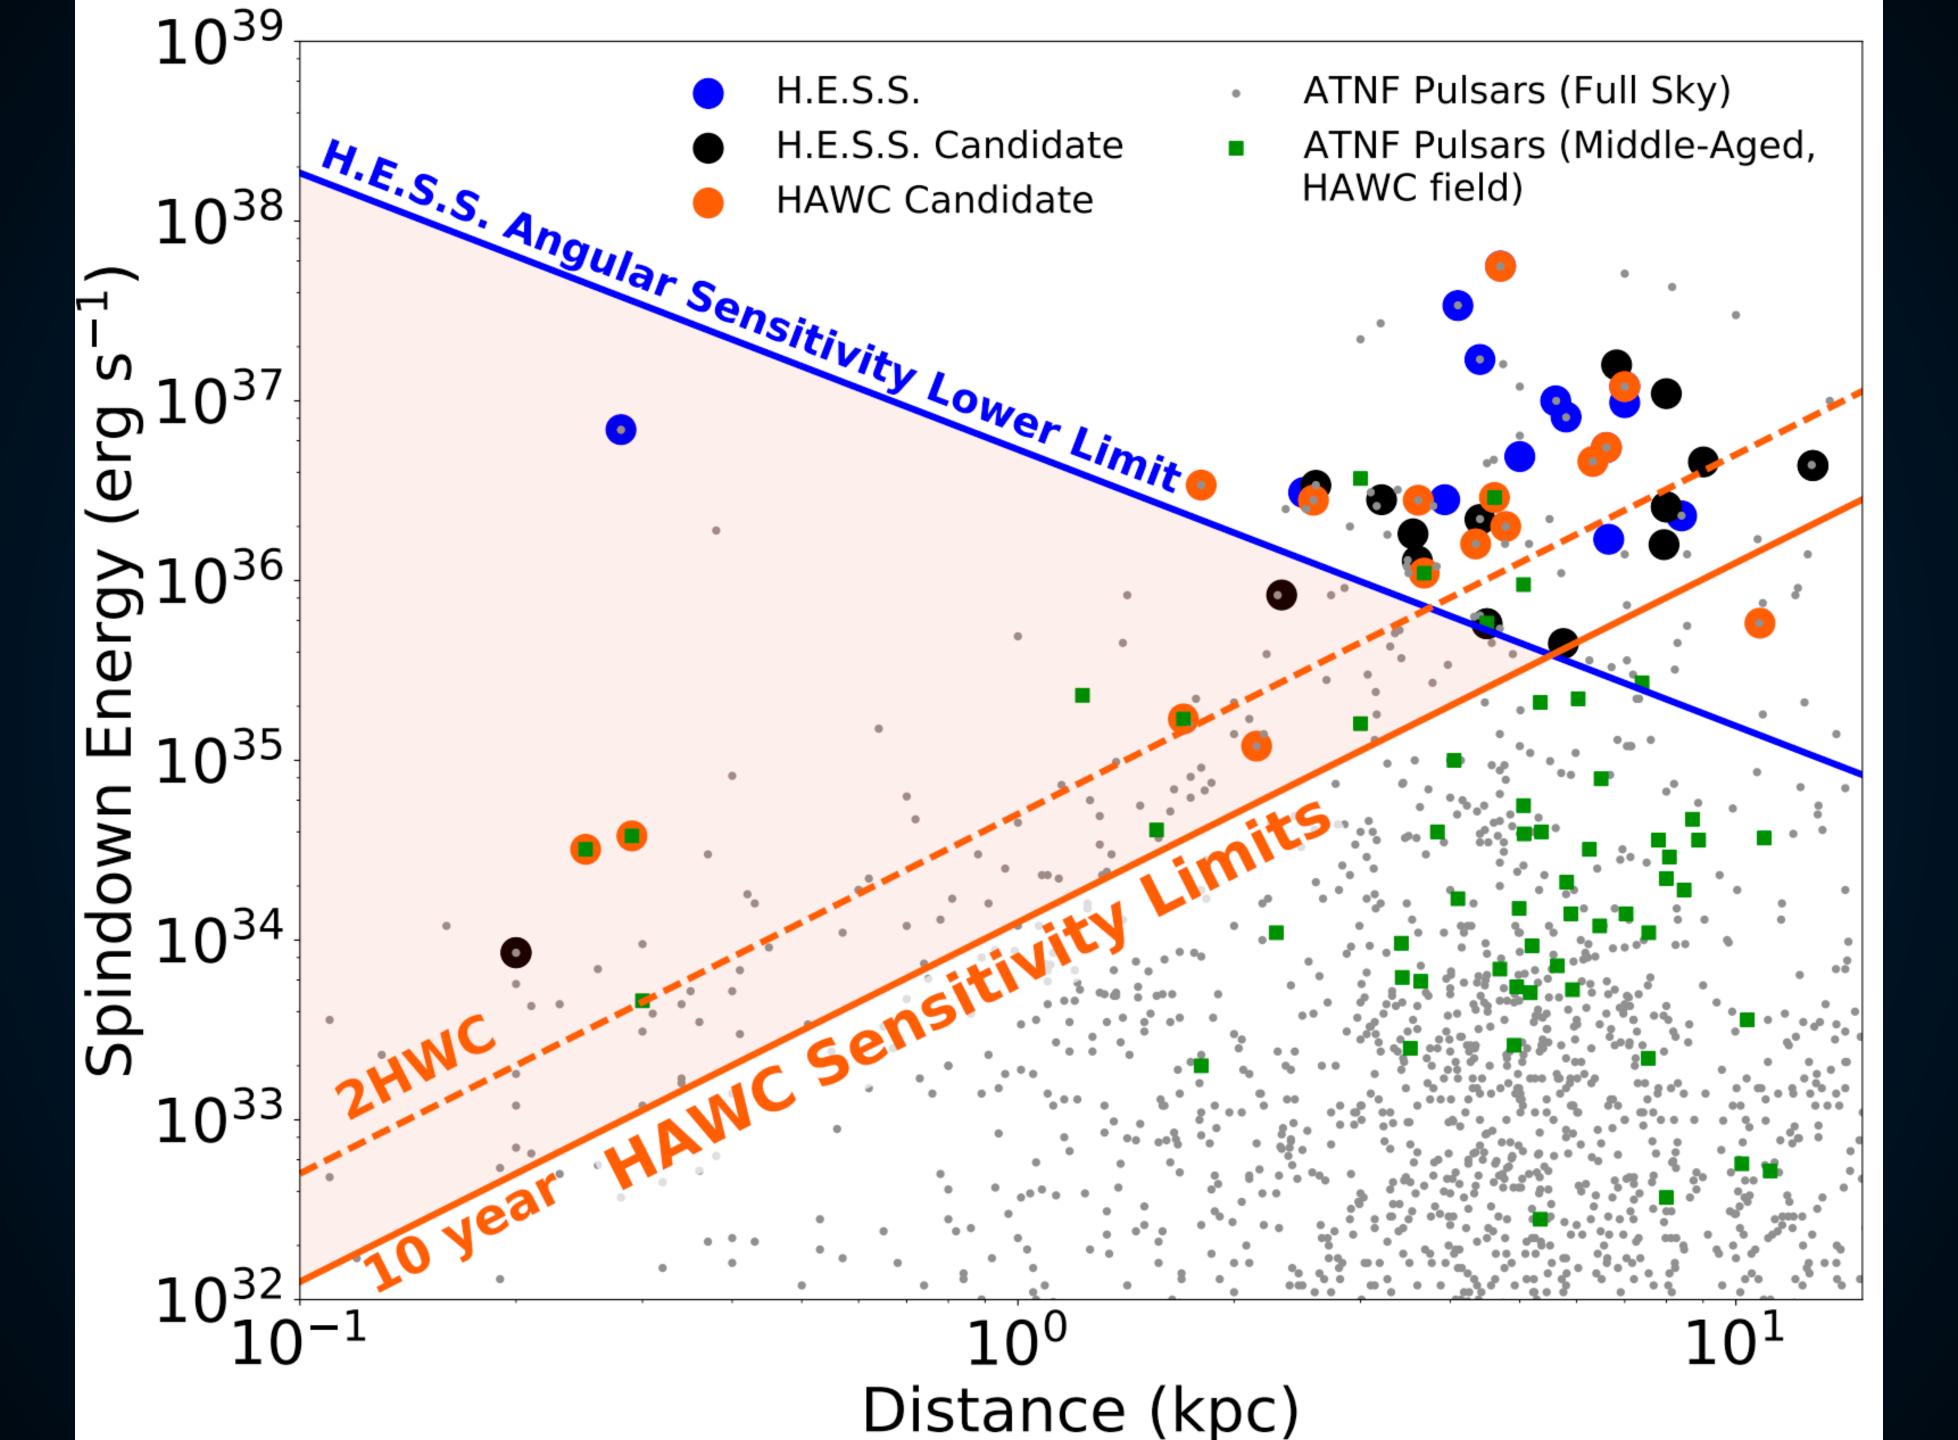

1/f pulsars are unseen in radio surveys.

- Correcting for the beaming fraction implies 56⁺¹⁵₋₁₁ TeV halos are currently observed by HAWC.
- However, only 39 HAWC sources total.
- Chance overlaps, SNR contamination must be taken into account.

IMPLICATIONS

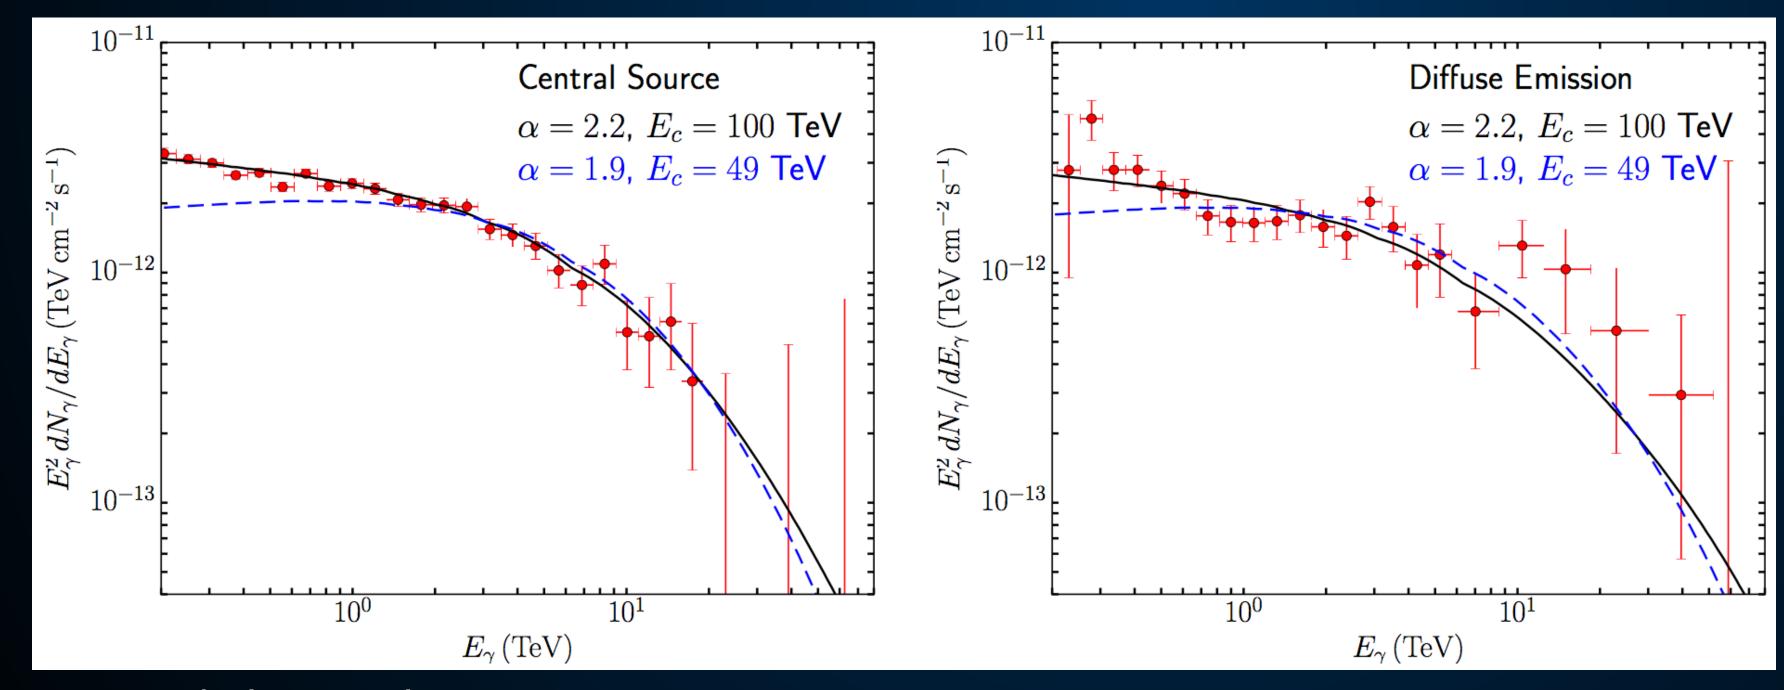

Milagro detects bright diffuse TeV emission along the Galactic plane.

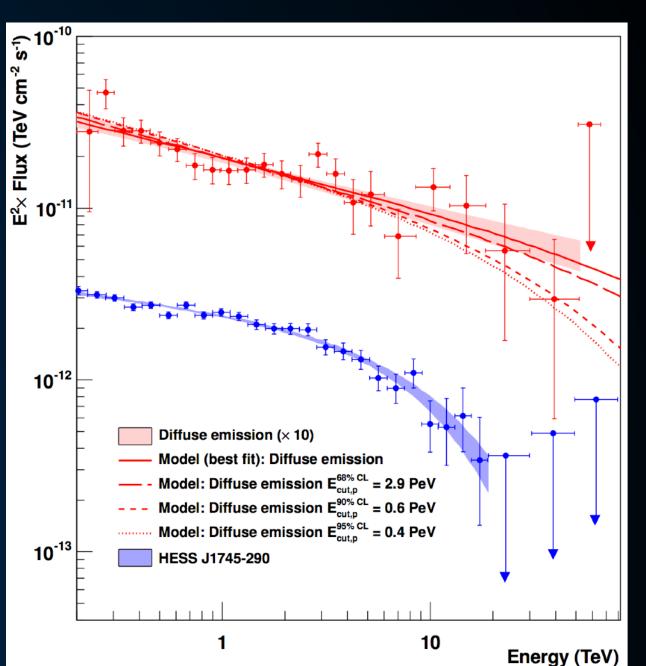

Difficult to explain with pion decay, due to steeply falling local hadronic CR spectrum.

The Geminga and Monogem TeV halo spectra naturally explain both the spectrum and intensity of this emission - No assumptions about diffusion! HESS observes 50 TeV diffuse emission from the Galactic center.

TeV halos explain the spectrum and intensity of this emission. No assumptions about diffusion!

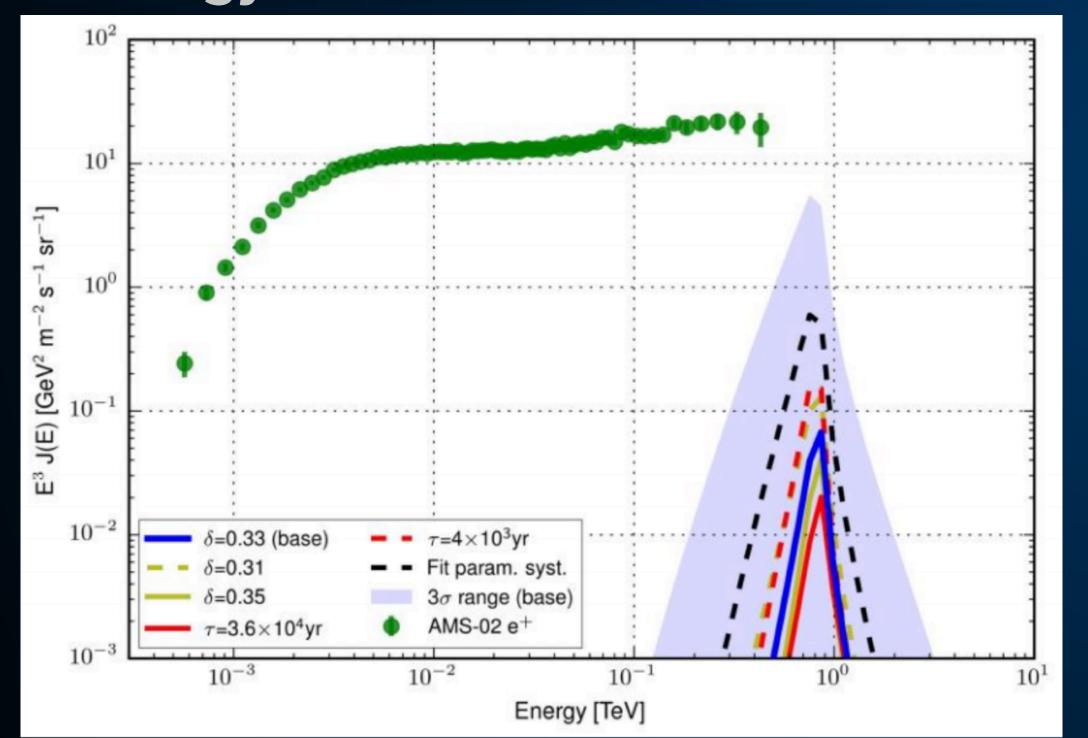

Implication III: The Positron Excess Positron fraction 10-1 O AMS FERMI □ PAMELA AMS-01 HEAT CAPRICE98 CAPRICE94 TS93 10^2 10 positron, electron energy [GeV]

Extrapolate Low Diffusion Constant UP to Earth

implies:

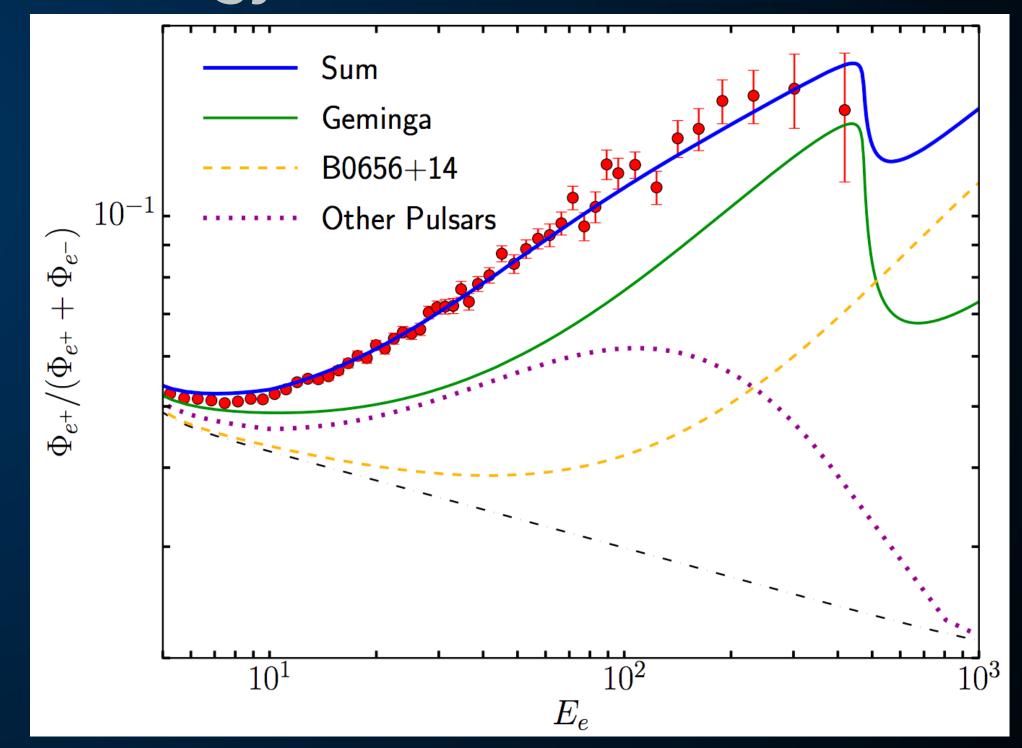

Low-Energy Positrons do not make it to Earth

Extrapolate High Diffusion DOWN to Earth

implies:

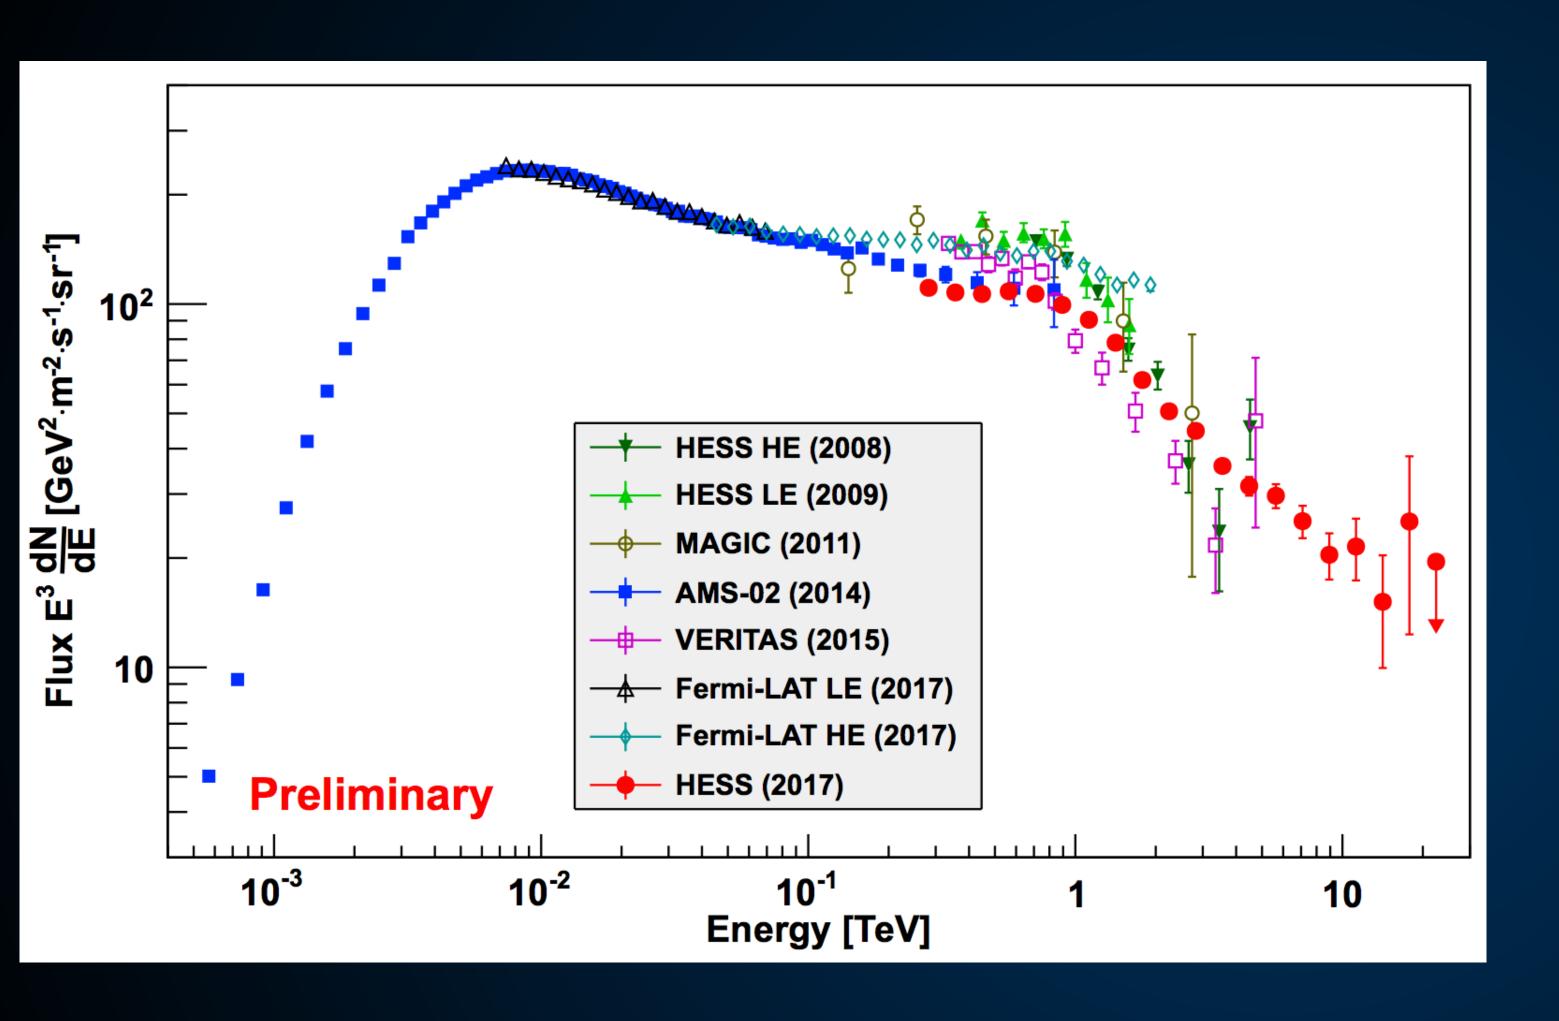

Low-Energy Positrons do make it to Earth

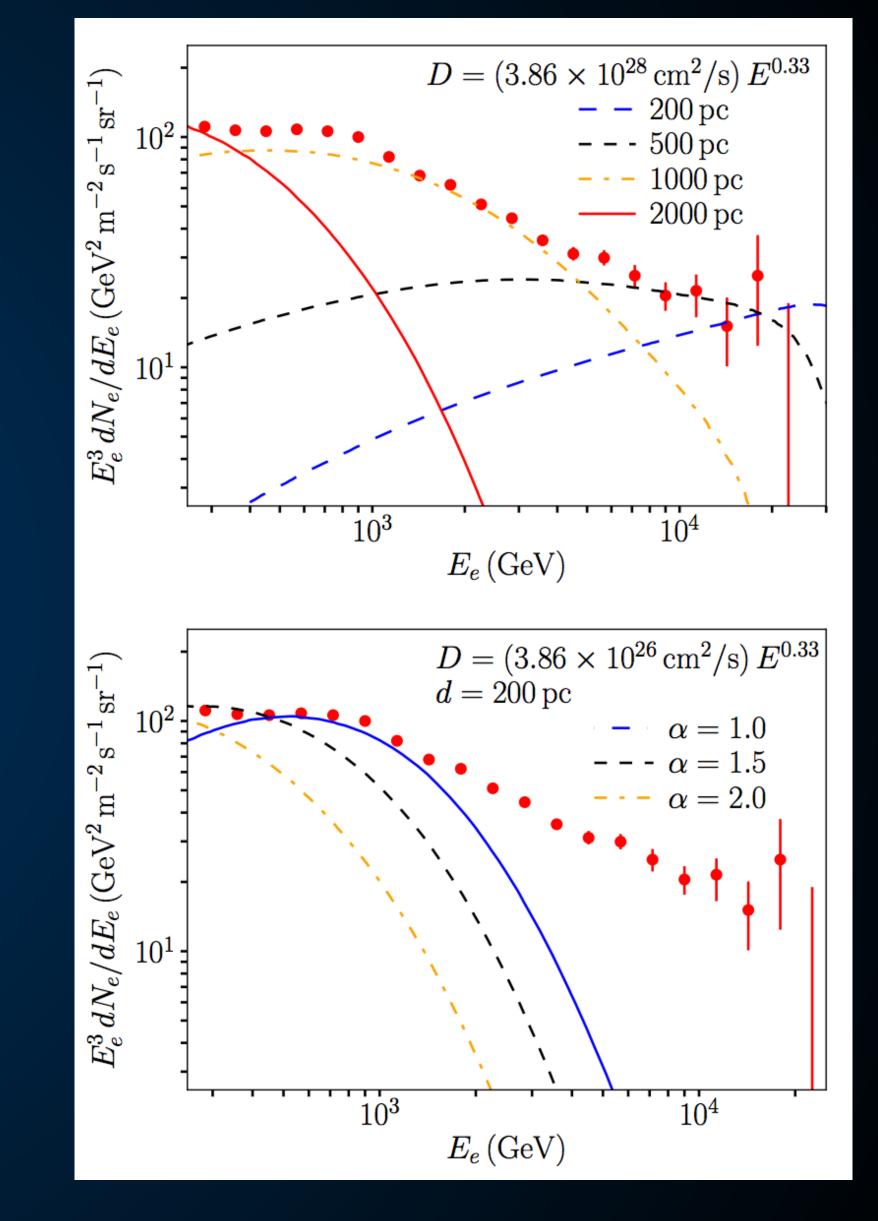

Hooper et al. (1702.08436)

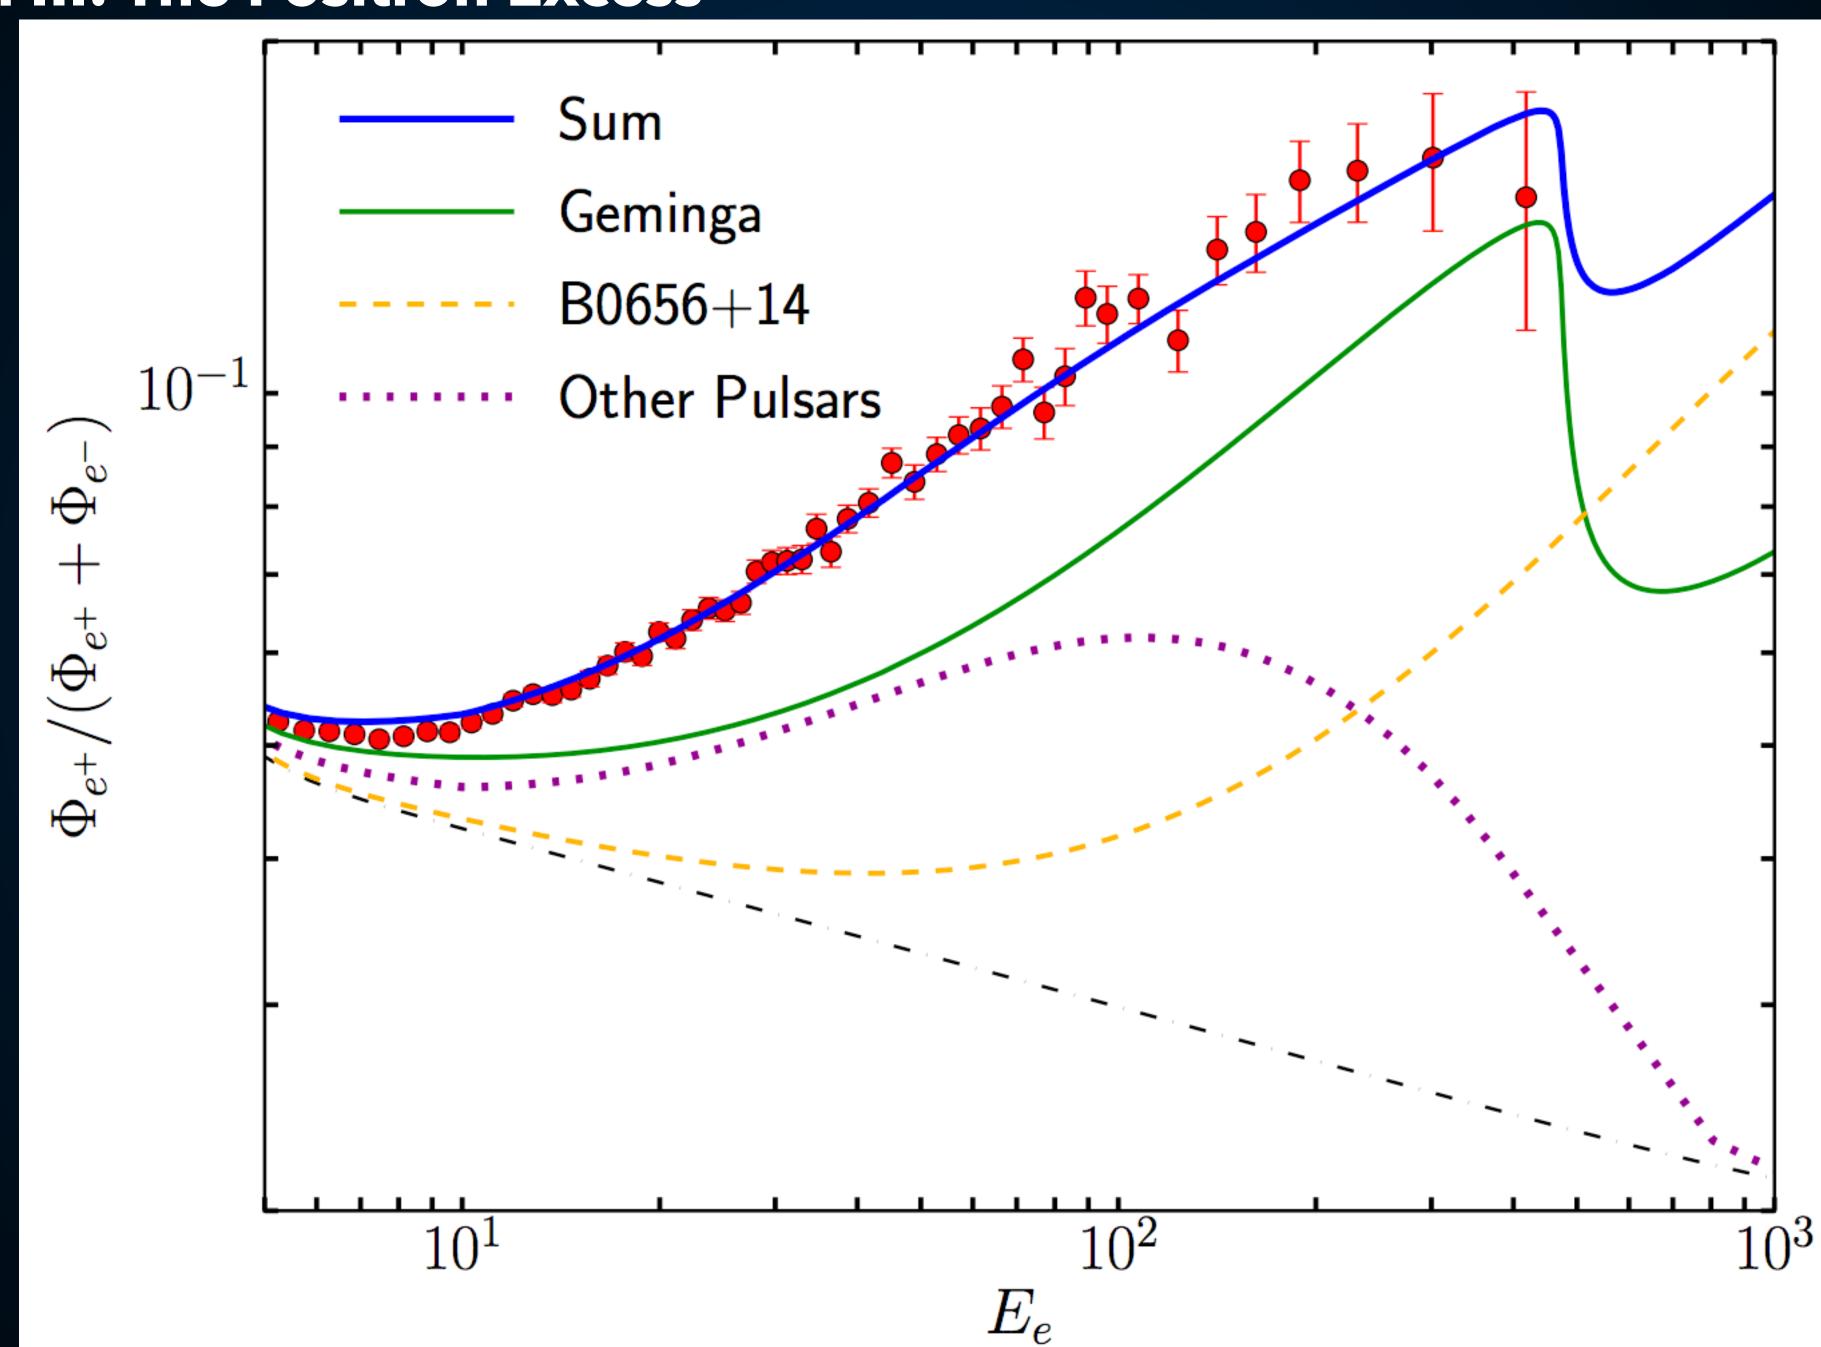

Profumo et al. (1803.09731)

Fang et al. (1803.02640)

- HESS Observations of 20 TeV electrons resolve this.
- If diffusion near Earth is low, then there is no source for these particles.

The Limited Assumptions in TeV Halo Observations

TeV Gamma-Ray Luminosity Roughly Proportional to Spindown Power

= Pulsars explain the Milagro TeV Excess

- + High Energy electrons trapped in TeV halos
- = Most HAWC Sources
 are TeV halos

- + Low energy electrons escape from TeV halos
- = Pulsars explain the positron excess

- + GC pulsars consistent with massive star formation
- = TeV halos explain the HESS pevatron

+ MSPs produce TeV halos

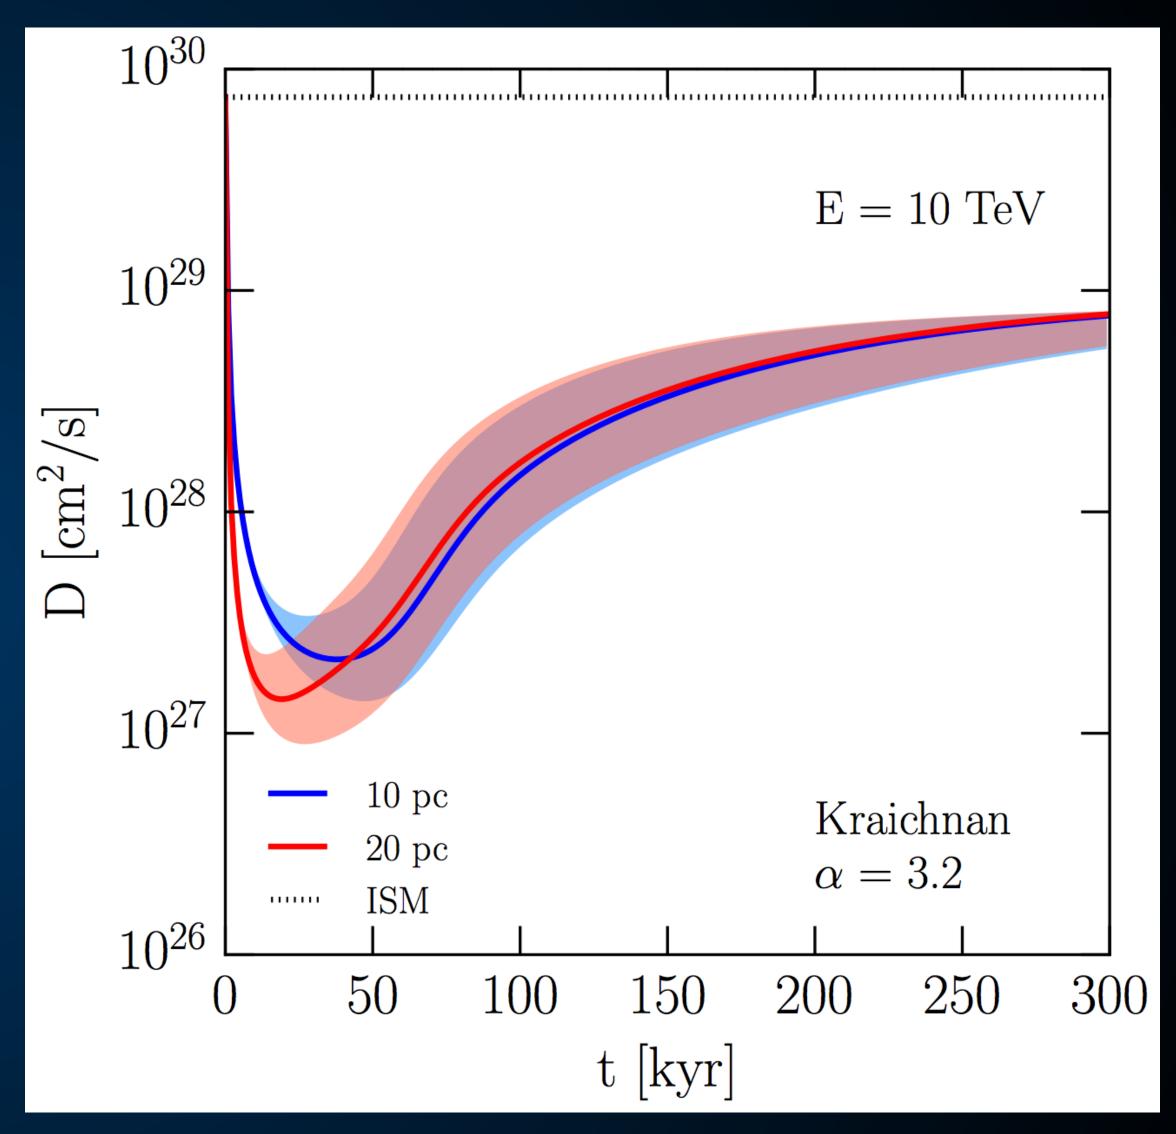

= New Population of Blind Search TeV MSPs

A First Model for TeV Halo Formation

• Cosmic-Ray leptons injected by the pulsar excite Alfven waves through the streaming instability.

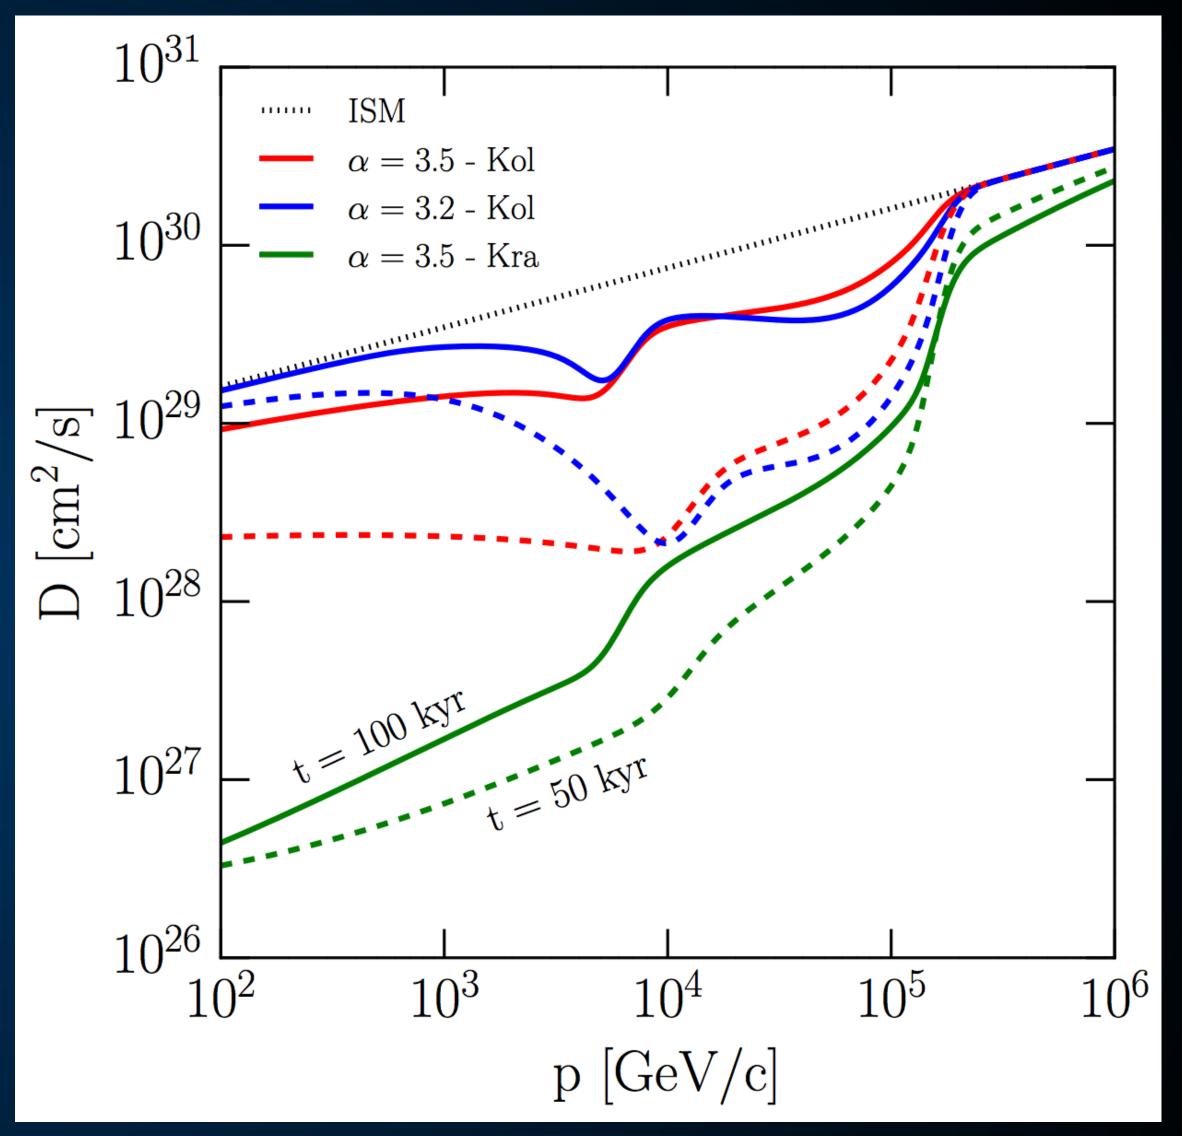

This drastically inhibits cosmic-ray diffusion near the pulsar – propagation can be inhibited by 1000x in young systems.

The duration of this effect varies significantly based on the assumed turbulence model, further observations necessary to constrain models.

Because most cosmic-rays are injected at high energies, high-energy diffusion is more inhibited.

Can significantly effect the typical Kolmogorov or Kraichnan turbulence spectra.

Conclusions (1/2)

TeV halos are a new dynamical object.

Have already observed ~20 objects; >100 inevitable

- Simple extrapolations of observed systems imply:
 - TeV halos dominate the TeV source number.
 - TeV halos dominate Milky Way diffuse emission.
 - TeV halos produce the positron excess.

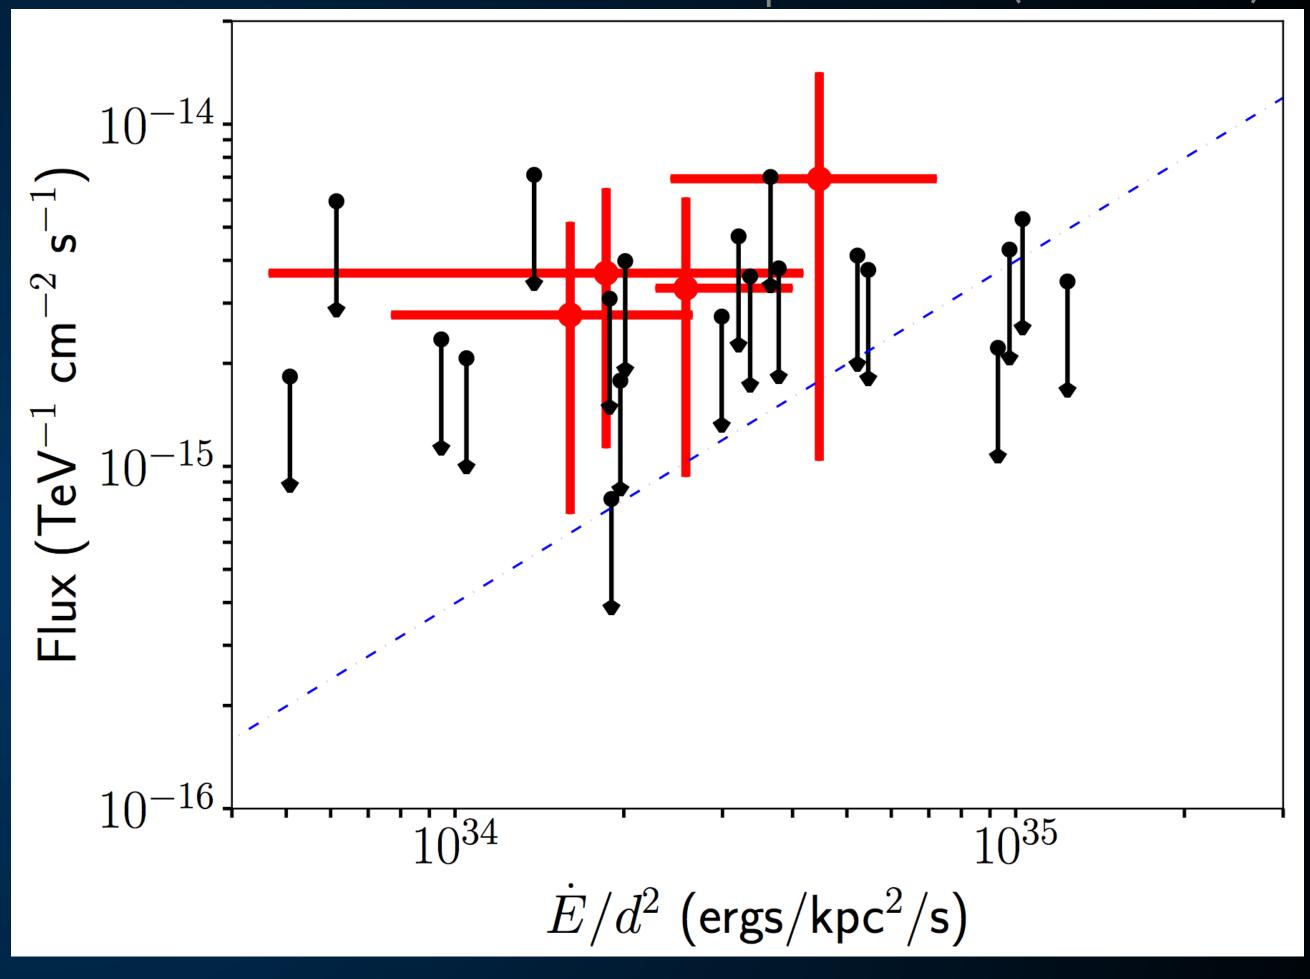

Conclusions (2/2)

TeV Halos will provide new insight into pulsar birth, death, and evolution, providing a new handle into the multi-wavelength study of neutron star dynamics.

TeV halos provide the first evidence for significant inhomogeneities in Galactic cosmic-ray propagation – new insights into cosmic-ray observations (e.g. AMS-02).

MSPs not expected to be bright enough to be individually detected.

Stacked analysis of MSP population provides some (2-3σ) evidence for TeV halo emission from MSPs.

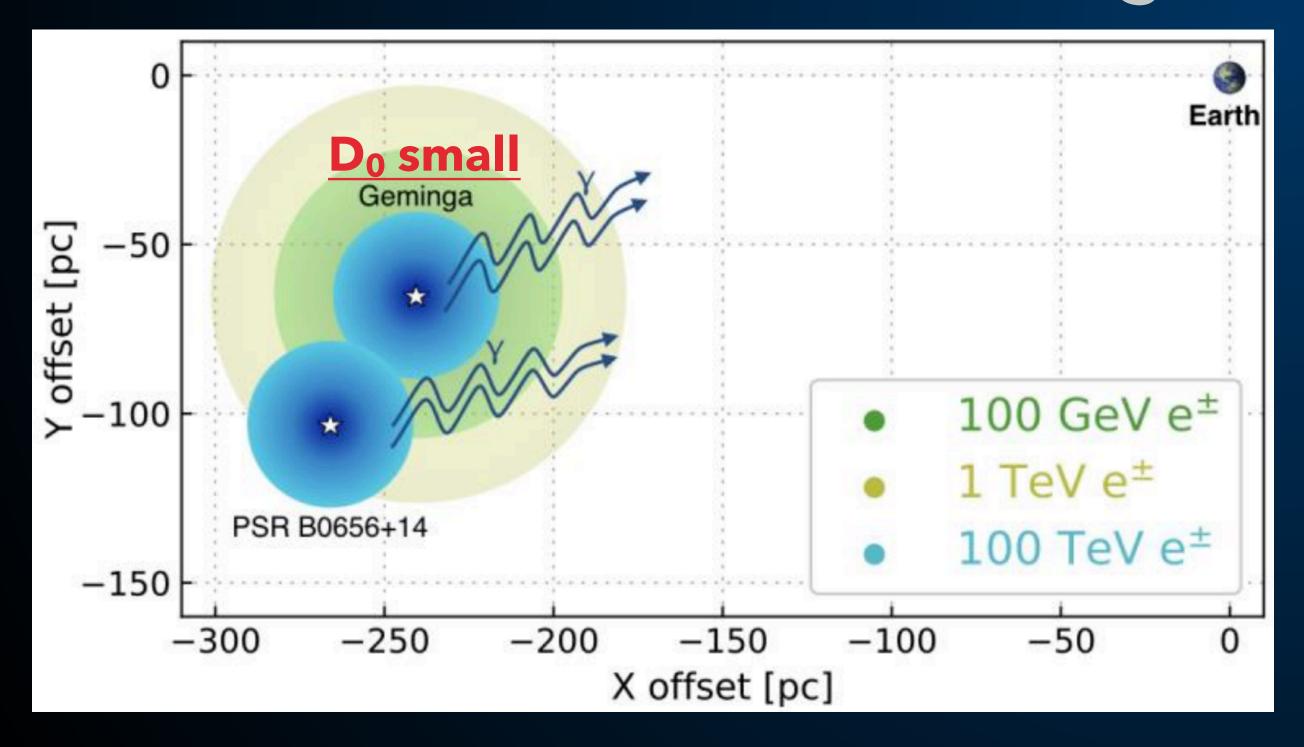

Would vastly increase the total TeV halo population, especially at high latitudes.

What we want to know is the average diffusion constant between Geminga and Earth.

What we have is:

Diffuse Constant Near Geminga

Diffuse Constant in Milky Way
